THE LIFE AND LABOURS OF
DR. WILLIAM HUNTER.

*A Discourse delivered at the Opening of
the Session 1844-45, in the Theatre of
St. George's Hospital.*

By ROBERT LEE, M.D. F.R.S. &c.

GENTLEMEN,—In the early part of the last century, Mr. John Hunter resided with his family, on a small paternal estate called Long Calderwood, in the parish of Killride, Lanarkshire. Five of his children died during infancy, and his eldest son, James, was cut off by consumption, in 1743, at the age of 28, after displaying the most amiable dispositions, and the greatest industry and talent as a student of medicine. There remained after his decease two sons and two daughters, one of whom, William, born on the 23d May, 1718, became the most consummate anatomist, and one of the most distinguished medical philosophers, that Britain has ever produced. He taught anatomy, physiology, and midwifery in London, with unparalleled success, for nearly forty years, established the celebrated school in Great Windmill Street, from which the school of St. George's Hospital emanated, and left to the University of Glasgow at his death in 1783, the largest and most valuable anatomical and pathological museum that had ever been formed. His younger brother, John, was born in 1728, and he became the greatest comparative anatomist and surgeon that ever lived. He was elected surgeon to St. George's Hospital in 1768, and died in 1793, near the spot where we are now assembled. The sister of William and John Hunter, Dorothea, was the mother of Dr. Mathew Baillie, physician to St. George's Hospital, and many years the first physician in London, whose Treatise on Morbid Anatomy has long been considered as one of the most valuable contributions to medical science, and was the first

work of the kind published in any country. In a letter from Sir Walter Scott to Miss Joanna Baillie, Dr. Baillie's sister, who has attained the most elevated rank in literature, the following eulogium is pronounced on his character:—"We have, indeed, to mourn such a man, as since medicine was first esteemed an useful and honoured science, has rarely occurred to grace its annals, and who will be lamented, so long as any one lives who has experienced the advantage of his professional skill, and the affectionate kindness by which it was accompanied."

An eminent writer has observed, that there were giants living on the earth at the time when John Hunter appeared,—Albinus, Haller, Monro, Camper, Cullen, Cheselden, Pott, and the members of the French Academy of Surgery. Though poor and friendless, and wholly destitute of patronage, William and John Hunter entered boldly and successfully into competition with this formidable host of scientific men, and by the unassisted force of their genius and industry, acquired a reputation which has not yet "gathered all its fame," but which, even at the present time, far surpasses that of all their illustrious contemporaries combined. To those who are about to engage in the study of medicine, it must be interesting and instructive to know, by what means the Hunters rose from the comparatively obscure and humble station in which they were born, to such unrivalled honour. It was the originality, the acute powers of observation and reasoning, the industry and learning, and the natural eloquence of William Hunter, which first enabled him to establish his own character as an anatomist, physiologist, and pathologist of the highest order, and thus to pave the way for his brother John. William Hunter not only laid the foundation of general pathology, which has been cultivated with so much ardour and success during the present century, but of all those splendid discoveries in comparative anatomy, and the absorbent system,

which were made by his brother John Hunter, and by Hewson and Cruikshank.

For the purpose, gentlemen, of exciting you to the most hearty, strenuous, and persevering exertions in the prosecution of those studies upon which you are entering at the commencement of another session, and to set before you a rare example of the most noble and disinterested devotedness to medical science, which we ought all to imitate, I shall now endeavour to point out to you some of those circumstances which principally contributed to form the peculiar character of the great founder of our school, William Hunter, and give a brief outline of his most important discoveries.

Being destined, like Boerhaave, for the Church, he was sent by his father to the University of Glasgow at the age of 14, where he spent five years in the study of the classics and philosophy. Not only did he acquire at this early period of life a thorough knowledge of the Greek and Latin languages, by which his taste was refined, and all the learning of the ancients was brought within his reach, but he acquired what was of equal importance, the power of writing the English language with the greatest perspicuity and force. So deeply was he impressed with the value of this accomplishment, that he was always accustomed in his lectures earnestly to recommend its attainment to his pupils as one of the principal means of acquiring respectability in the medical profession. "Good language, good composition, good writing in every sense," he said, "depends very much on practice and habit. All good writers allow this. The best of them generally speaking confess, that though all their valuable works cost them a great deal of labour, yet that they found the labour of being an author become much lighter after some practice. Now a student who writes out lectures (from short notes) is by that very practice acquiring a facility of writing upon subjects in his profession; of describing all sorts of natural and morbid appearances, of reasoning upon these, of putting his thoughts into the most distinct order, and of expressing them in the most clear and proper language. Besides the honour which arises from the character of being a good writer, we observe in fact that every man in the profession who has been a considerable writer, has in consequence become a considerable practitioner likewise, and the public has always, at least, done justice to respectable writers."

William Hunter attended not only the classes of languages and philosophy at the University of Glasgow; the lectures of Prof. Dunlop, an eminent Greek scholar, of Simson, the restorer of the ancient geometry, and Dr. Francis Hutchinson, the eloquent author of the work on the Beauty of Virtue,

were additional incentives to the strenuous exercise of his faculties, especially as he had the advantage of being stimulated by the example of many kindred spirits, afterwards of great celebrity in letters and science—such as Dr. Mathew Stewart, one of the greatest mathematicians of the age, Dr. John Douglas, Bishop of Salisbury, Dr. Adam Smith, and others of distinguished name. The very Rev. and learned John Lee, D.D., Principal of the University of Edinburgh, has informed me within the last few days of these circumstances, and likewise that at this time various literary societies or clubs existed in Glasgow (under the names of the Eleutherian, the Sophocordian, the Anti-Cappadocian, the Triumpherian) which encouraged great freedom of discussion, and alarmed many serious persons, because they were conceived to give a loose to fancy and to audacious speculations, without being moderated by solid principles. Woodrow says, that it was the practice of the members to *declaim against reading, and cry up thinking*. John Hunter was only four years of age at the time, otherwise we might have inferred that he had been among them; but it cannot be denied that these associations, though not universally guided by prudence, had a tendency to elicit the efforts of powerful minds, and lead to discoveries which, but for such excitement, might have been long unknown. Professor Simson patronized some of these clubs, and, indeed, one of them was called by his name. The effect of the system pursued at Glasgow was allowed by men of discernment, not prepossessed in favour of that University, to have been this—that "whereas among those who studied at that time in Edinburgh, a greater proportion rapidly obtained a marked superiority, the character of the students at Glasgow in general was entitled to the credit of being more steadily intent on the pursuit of solid learning, so that there were few instances of relaxation in the habits of close application."

It was doubtless in a great degree owing to this intellectual discipline, this mental culture, to the knowledge which William Hunter then acquired of the laws of evidence and the rules of investigation, that through life he would take nothing for granted—he examined every thing for himself—and that no statements proceeding even from the highest authorities would he admit as facts, until their truth was clearly demonstrated: even from established truths his conclusions were drawn with the utmost caution. So numerous, varied, and exact were the observations and researches which he always made on every subject he investigated, and so rigorously were the inferences deduced from the facts he had ascertained,—so strictly did he adhere to the inductive method of reasoning, that it would be difficult, nay, I believe

it would be impossible, to point out any material error in his writings, or discover a statement there made, which it had been necessary for him to modify or to retract. "Good heavens," he said, "what pains is required to do any thing with tolerable accuracy!" It was not only in the observation of natural phenomena that this accuracy was displayed, but in his controversial writings the same integrity and inflexible regard for truth are every where equally conspicuous. It is to this striking feature of his character that I am anxious your attention should be directed above all others. There is nothing that ought to excite in our minds such abhorrence and disgust as false statements made from whatever cause or motive in medical writings.

In hypotheses, theories, or mysticisms, he never indulged like many of his predecessors and contemporaries, but confined himself scrupulously to the discovery and interpretation of facts. With a mind so constituted, and so prepared for the investigation of truth, he could not fail to discover that fallacious theories transferred from chemistry, mechanics, and other departments of science, to medicine, had prevailed in all ages, and that a more perfect knowledge of the human body in health and disease was the only sure foundation of rational pathology and practice. The doctrine of Hippocrates, says Sir Gilbert Blane, which referred all diseases to defect or vitiation of the four humours, blood, phlegm, black bile or yellow bile, and the theory of Galen, grounded on the cardinal qualities of heat and cold, moisture and dryness, and other theories proposed to explain all the phenomena of disease, William Hunter discovered at once to be gratuitous assumptions. A little before his time the mechanical powers of the stomach were subjected to experimental research, and Dr. Pitcairn gravely affirmed that he found this viscus in the human subject to exert a force equal to 12,900 pounds in compressing the food in the process of digestion. Our present knowledge enables us to say that he was at least 12,900 miles from the truth. Others, conceiving that chemical power had the chief agency in this function, endeavoured to prove that the changes in the food were produced by heat and fermentation, forgetting altogether the influence of the vital principle. The peculiar sagacity and precision of William Hunter's mind detected at a glance the hollowness of such delusions, and in his lectures he thus facetiously exposed their folly. "Some physiologists, gentlemen, will have it that the stomach is a mill; others that it is a fermenting vat; others, again, that it is a stew-pan; but in my view of the matter it is neither a mill, a fermenting vat, nor a stew-pan, but a stomach, gentlemen, a stomach."

At no former period was the study of medical logic ever more necessary than at the present time, when every species of delusion prevails both in the theory and practice of physic.

Empiricism, whatever form it assumes, and by whatever term it is designated—homœopathy, hydropathy, mesmerism, or animal magnetism, always rests chiefly on superstition and credulity, or imposture, and the picture of it drawn by William Hunter one hundred years ago, represents its present state in Britain much more correctly than many would at first believe. "The uncertainty of cure, both of physic and surgery," he says, "gives the ignorant and hardy empiric frequent opportunities of exulting over science. Ignorance is rash and fearless; knowledge is always cautious and circumspect. The first, amidst much mischief, boasts now and then a random cure; the other, though active when there is a prospect of success, is frequently restrained by the fear of doing harm. At the same time, by this caution, and a proper view of the bounds of the art, the rational practitioner enjoys much secret satisfaction, and has frequently in his turn ample cause of triumph over empiricism. The preceding history (it was a case of aneurism of the aorta about to burst) might illustrate and justify this remark. Yet even in this case empiricks of all kinds were pressed upon him (the patient) who tempted and tortured him with vain promises. They understood no more of the case than that it was thought desperate; they knew they could lose no reputation; they were conscious they could not feel remorse; and were desirous at all events of being in fortune's way. A foreigner insinuated that it was a case which English surgeons did not understand, and pressed warm bathing and the Montpellier method of curing the pox. A quack recommended his pill, which he said was so peculiarly adapted to inward swellings, that none of them could withstand its operation. An old woman would engage to cure him with her herb-poultice, which she said, though she was turned of threescore-and-seven years, had never once failed her in such a case: and the poor man could not help having a partiality for the remedy, when she protested there were above thirty herbs in the composition, and that she gathered them all with her own hands. Another, who knew that an aneurism is seldom curable by any other means, proposed the operation: but the patient was prevailed upon to reject the proposal, when he understood that it must be a very painful operation, and that he could not expect that his life would be comfortable after the great artery was tied so near the heart."

At the age of 19, having relinquished his

intention of entering the church, William Hunter resolved to devote himself to the medical profession.

In 1737, he became a pupil of Dr. William Cullen, then recently established at Hamilton in Lanarkshire, whose disposition, genius, and love of knowledge, were congenial with his own. This was another circumstance which contributed powerfully to the development of his peculiar talents; for though Dr. Cullen was addicted to speculation, and adopted hypotheses to explain the symptoms of disease, which are now rejected as unfounded, it is certain that no physician, as his biographer observes, "inculcated more strongly the doctrine, that all our knowledge of nature is derived from experience, or who took greater pains to distinguish between well-ascertained matters of fact and the assumptions and conclusions of hypothetical reasoning." There was no man in the last century whose writings, lectures, and example, had a greater influence on the opinions and practice of the members of the whole medical profession in this country, and on the general progress of medical science, than Dr. Cullen; or who possessed the power in a higher degree of rousing his pupils to exertion, and of infusing great ardour into their minds.

William Hunter passed three years in the family of this excellent friend and preceptor, and these, as he has been often heard to acknowledge, were the happiest years of his life. The subjects which, at this early age, most deeply engaged his attention, may be readily understood by the following passage in one of his letters addressed to Dr. Cullen a few years after their separation:—"Well! how does the animal economy appear to you, now that you have examined it, as one may say, with precision? I have good reason to put the question to you: because in my little attempts that way, since I began to think for myself, nature, where I am best disposed to mark her, beams so strong upon me that I am lost in wonder, and count it sacrilege to measure her meanest features by my largest conceptions."

At the age of 47, he thus addressed himself to Dr. Cullen: "I am resolved never to be much richer than I now am. I am independent, and wish to do something that shall be mentioned when the few years which I have to live are gone. Now, you shall see to what I purpose all this. I should like to be joined with you in the end of life as in the beginning."

There is reason to believe that his acquaintance with Dr. Cullen was one of the most fortunate incidents of his life, and I am convinced, from experience, that there is no circumstance which exercises so powerful and so lasting an influence upon the mind of a medical student, as the dispositions and

characters of those with whom he first associates. Nothing tends so much to lighten the toils of mental exertion, to promote intellectual improvement, and to cheer the loneliness of the student's life, when separated from his friends and relations, than the society and conversation of those who are engaged in the same pursuits, who are devoted to the acquisition of professional knowledge, and whose conduct is regulated by pure and honourable principles. Nothing tends more certainly and speedily to utter degradation and ruin than an intimacy formed with those who are idle, frivolous, and dissipated, and whose tastes are low and depraved. The fairest prospects in life have often been blasted at the outset by evil communications.

In 1741, at the age of 23, William Hunter came to London for the purpose of completing his medical education, and afterwards returning to Hamilton to join Dr. Cullen in practice. He entered as a surgical pupil of St. George's Hospital, and it was here, "attending the sick and dissecting the dead," as he expressed it, "that he discovered the direct road for becoming truly great in his profession." The winter before, he had spent at Edinburgh, attending the medical lectures delivered in the University, and especially those of Dr. Monro on anatomy. From the account which he has given of the manner in which anatomy was then taught by one of its most distinguished professors, you will be enabled fully to estimate the immense advantages which are now enjoyed, compared with those which were possessed by students a century ago, when there was no school for practical anatomy in London. "There," he says, "I learned a good deal by my ears, but almost nothing by my eyes, and therefore, hardly any thing to the purpose. The defect was, that the professor was obliged to demonstrate all the parts of the body, except the bones, nerves, and vessels, upon one dead body (the course lasting six months). There was a fœtus for the nerves and blood-vessels; and the operations of surgery were explained to very little purpose upon a dog. "All was harangue, and very little was distinctly seen."

This unprofitable mode of teaching anatomy was probably the cause why he always took such pains to inculcate "the necessity of striving to get clear ideas of every thing." "The eyes and ears of the student," he said, "ought to be employed in that service only. He is first to understand; let him remember as he can; and, to say the truth, as it is a difficult task to remember what we do not understand, so it is hardly possible to forget what we clearly comprehend: so that, in getting distinct and clear ideas, especially of the objects of our senses, we are taking the

best method of fixing them for ever in the memory."

Dr. Smellie, also a native of Lanarkshire, was at that time the most eminent teacher of midwifery in London, and the greatest systematic writer on the subject in existence. William Hunter resided with him for a short period to acquire a practical knowledge of midwifery, and then accepted of an offer made to him by Dr. Douglas, the anatomist, to assist him in his dissections, and superintend the education of his son: his classical attainments led to this appointment. A new career was thus happily opened to his talents and ambition, and he resolved to remain in London, and dedicate his life to the practice of midwifery and the improvement of anatomy and pathology. To prepare himself for the duties of an anatomical teacher and accoucheur, he determined to subject every part of the human body to the severest scrutiny, and to acquire the most minute knowledge that could be obtained by dissection of the intimate structure of every organ. He allowed nothing to interfere with his resolution to master his profession,—pleasure and amusement could not allure him for a moment from the dissecting room and the wards of the hospital. He drudged, like Selden, days and nights, and grappled with and conquered all the difficulties which opposed his progress, and would have overwhelmed less resolute minds. He knew that knowledge could only be acquired by labour, and that labour was the only price of solid fame. Zealously and steadfastly he pursued the object which he had in view, and set an example of vigorous, patient, laborious industry, which has never been surpassed, and which all must follow who are eager to attain legitimately the highest rank and honours in the medical profession; and, what is of still greater consequence, and a still higher object of ambition, who would possess the power to be useful to their fellow creatures, by removing and alleviating their diseases. The fruits of such unwearied efforts soon became manifest, and at the age of 25, only two years after his arrival in London, he presented to the Royal Society an essay on the Structure and Diseases of Articulating Cartilages, which is now admitted by all competent judges to contain every fact of importance which has yet been discovered respecting the anatomy of the human joints, and an accurate outline of some of their most dangerous diseases. I have the authority of Sir B. Brodie for asserting, that in this essay, which has been published in the 42d volume of the *Philosophical Transactions*, for 1743, William Hunter "anticipated all that Bichat wrote sixty years afterwards respecting the structure and arrangement of the synovial membranes." Of the truth of this you will readily

be convinced by the following passages. After accurately pointing out the peculiarities of each articulation, and the varieties of mechanical composition calculated to all the varieties of motion in the human body, and the intimate structure of cartilage, he thus describes the synovial membranes of the joints:—"We are told by anatomists that cartilages are covered with a membrane named perichondrium. If they mean the cartilage of the ribs, larynx, ear, &c. then indeed such a membrane is very conspicuous; but the perichondrium of the smooth articulating cartilages is so fine and firmly braced upon the surface, that there is room to doubt whether it has been often demonstrated or rightly understood. This membrane, however, I have raised in pretty large pieces after macerating, and found it to be a continuation of that fine smooth membrane that lines the capsular ligament folded over the end of the bone from where that ligament is inserted. On the neck of the bone, or between the insertion of the ligament and border of the cartilage, it is very conspicuous, and may be pulled up with a pair of pincers; but where it covers the cartilage, it coheres to it so closely, that it is not to be traced in the recent subject without great care and delicacy. In this particular it resembles that membrane which is common to the eyelids and the fore part of the eye-ball, and which is loosely connected with the albuginea, but strongly attached to the cornea. From this description it is plain that every joint is invested with a membrane, which forms a complete bag, and gives a covering to every thing within the articulation, in the same manner as the peritoneum invests not only the parietes, but the contents of the abdomen."

But William Hunter has not merely given in this paper the best description that has ever appeared of the structure of the human joints; he has likewise given an excellent outline of the morbid anatomy of the synovial membranes and the cartilages, and proved that inflammation and ulceration of these textures may exist independently of disease of the bone. It thus appears, that in this hospital the investigation of the pathology of the joints had commenced, and made considerable progress, a century ago.

"So far as I have had opportunities of examining diseased joints, either after death or amputation, I have found, according to the nature and stage of the disease, the cartilage in some parts reddish and lax, or soft and spongy, or raised up in blisters from the bone, or quite eroded, and perhaps the extremities of the bone carious, or, lastly, a bony ankylosis formed; but I could never see, nor indeed hear, of the least appearance of an exfoliation from the surface of the cartilage. Now if we compare the texture and

morbid phenomena of those cartilages together, all the diseased appearances will admit of as rational a solution as perhaps any other part of the vitiated œconomy."

"It appears from maceration that the transverse fibres are extremely tender and dissoluble, and that the cohesion of the parts of the strait fibres is stronger than their cohesion with the bone. When a cartilage therefore, is inflamed, and soaked in purulent matter, the transverse or connecting fibres will the soonest give way, and the cartilage becomes more or less red and soft, &c. If the disorder goes on a little longer, the cartilage does not throw off a slough, but separates from the bone where the force of cohesion is least, and where the disease soon arrives by reason of the thinness of the cartilage. When the bone is thus exposed, the matter of the ulcer, or motion of the joint, corrodes or abrades the bony fibres."

When this paper was written, John Hunter was only 15 years of age, and did not enter his brother's dissecting-room till five years afterwards. J. Hunter came to London in 1748.

About the same time (1743) that this essay appeared in the *Transactions of the Royal Society*, Dr. W. Hunter commenced that elaborate investigation of the absorbent system, which terminated about 1746 in the important discovery, that the lymphatic vessels are absorbing vessels all over the body, "that they are the same as the lacteals; and that these together constitute one great general system dispersed through the whole body for absorption; that this system only does absorb, and not the veins; that it serves to take up and convey whatever is to make or to be mixed with the blood, from the skin, from the intestinal canal, and from all the internal cavities or surfaces whatever." The lymphatics had generally been regarded before this as veins to return the lymph from such arteries as were too small to admit the red blood or the serum. The anatomists of Europe, for one hundred years before, were of opinion, that the lymphatic system was wanting in birds and fishes; but William Hunter, having discovered the importance of the absorbent system in man and in quadrupeds, could not rest satisfied that it was wanting in the other two great classes of animals, and kept that object, and every thing else that could throw light on the absorbent system, constantly in his view. It was entirely in consequence of this deep conviction in the mind of William Hunter that his brother's attention was called to the subject, and that he was led to search for the lymphatics, and to discover them first in birds and then in a crocodile. Mr. Hewson afterwards, by a continued course of observation and experiments made in the dissecting rooms, under the direction and at the expense of William Hunter, demonstrated

the lacteals and lymphatics both in birds and fishes, "which confirmed the use and importance of the absorbent system in the human body, and in comparative anatomy was one of the greatest improvements that could have been made to establish the universality of nature's laws in animals." It was at the express desire, and under the enlightened direction, and in the house of William Hunter, that Mr. Cruikshank, at a still later period, traced the ramifications of that system in almost every part of the human body. Great honour is undoubtedly due to these three anatomists for their minute dissections of the absorbent system, but it must not be forgotten, that they were directed, and animated, and sustained in the pursuit by the philosophical and comprehensive mind of William Hunter, and that the whole investigation originated with him. He did not set too high a value upon the discovery of the functions of the lymphatics when he asserted, that it was the greatest, both in physiology and pathology, that anatomy had suggested since the discovery of the circulation of the blood.

He was now involved in all the harassing cares and duties of an accoucheur and teacher of anatomy and midwifery, but his scientific pursuits were not interrupted; and from 1746 to 1783 he not merely delivered every winter the most complete course of lectures on anatomy that had ever been given in London, but continued at intervals to enrich the science of medicine with the most valuable contributions it had ever received. Having no family, and setting no value upon money, except as a means of acquiring knowledge and communicating it to others, every moment that could be spared from the active duties of his profession was devoted to the minute investigation of the human body, and in making the finest preparations to illustrate the structure and functions and diseases of the different organs. Most of these preparations are still preserved in the Museum at Glasgow; and I am assured by Mr. Wharton Jones, who has examined those of the human eye with care, that they afford proofs of the utmost anatomical accuracy and delicacy. Those which shew the vessels of the pupillary membrane and crystalline capsule have never been surpassed in accuracy and minuteness; and this Mr. Jones considers to have been the finest point in anatomy at that time, and first made out by William Hunter. He has thus described these vessels:—"I do not know that any person has taken notice of a circumstance relating to the vessels of the membrana pupillæ and the crystalline capsule, which I have observed, and can demonstrate by injections, both in the human fœtus and in that of the quadruped; and as I am upon the subject, I will give the observation here

in a few words. The artery of the crystalline capsule does not terminate at the great circle of that humour. Its small branches pass that circle, and run a very little way on the anterior surface of the crystalline humour, before the points of the ciliary processes; then they leave the humour and run forwards, supported on a very delicate membrane, to lose themselves in the membrana pupillæ. The artery, therefore, that passes through the body of the vitreous humour, goes first to the crystalline capsule, and then to the membrana pupillæ. The membrana pupillæ receives two different sets of arteries, one larger, from the iris, and the other much smaller, but very numerous, from the crystalline capsule. When the membrana pupillæ exists, there is a fine vascular membrane all around, which passes on the posterior aqueous chamber, from near the edge of the crystalline humour to the edge of the pupilla."—*Med. Comment.* p. 63.

This description, Mr. Jones informs me, was not understood by succeeding anatomists, and a part of it was merely noticed by them. M. Jules Cloquet's description especially is very imperfect compared with that of W. Hunter. The full description by him has only recently been brought to light, by the German anatomist, Henlé. All this proves that William Hunter, as a minute and accurate anatomist, was far superior to Albinus, who first described the pupillary membrane, and was not inferior to any anatomist then in Europe.

It would exhaust your patience if I were to do much more than enumerate the various contributions which he afterwards made to anatomy, pathology, and midwifery. His papers have never been collected. The greater number of them are now upon the table; they are all the most valuable monographs that have ever been published on the different subjects of which they treat.

In 1747, he discovered the ducts of the human lachrymal gland. About the beginning of November, 1752, in the presence of M. Gallie and some others, he injected the vas deferens with mercury, and by that method filled the whole epididymis, and the tubes that come out from the body of the testis to form it; and observed in this operation, that the mercury continued to run, and the body of the testis to become gradually more turgid and heavy, for some time after the external parts were completely filled. He shewed this preparation next night at his public lecture, and said that he believed we should find the internal tubuli likewise filled, but that he would not venture to open it till he had got another, lest he should spoil what was already a valuable preparation. "I desired my brother," he says, "to lose no opportunity of making the

trial." This was communicated as a piece of anatomical news to Dr. Donald Monro, then at Edinburgh, by a letter from Dr. Garrow, physician at Barnet, some time in the same month. In some such time as a week or a fortnight after the first public demonstration, my brother made the trial, and succeeded. He shewed me the testis opened, and the tubular internal substance very generally filled with mercury. This preparation, which I still preserve, I shewed at my public lecture that very evening, with marks of being well pleased with the discovery. In my next course of lectures, viz. February, &c. 1753, and in every course since that time, I have shewn the same, and some other preparations of the same kind, and always gave the history of the discovery, to avoid taking that share of it from my brother which belonged to him.—*Med. Comment.* Lond. 1761, p. 1.

In 1754 he first described retroversion of the uterus.

In 1757, History of an Aneurism of the Aorta, with some Remarks on Aneurism in general.—*Med. Obs. and Inquiries*, v. i. 323.

In vol. ii. An Account of a Diseased Tibia, and Remarks on the Symphysis Pubis.

In 1757, in the second volume of the Medical Observations and Inquiries, he published a paper entitled, "The History of an Emphysema, and Remarks on the Cellular Membrane and some of its Diseases." He first pointed out, in this essay, what he had discovered thirteen years before, the distinction between the adipose tissue and the common reticular or cellular membrane, which is now admitted by all anatomists to be well founded. "Wherever there is fat in the human body," he says, "I apprehend that there is a particular organization, or glandular apparatus, superadded to the reticular membrane, consisting of vesicles or bags, for lodging the animal oil, as well as vessels fitted for secretion; so that I would compare the marrow in the bones to the glandular or follicular parts of the fat or adipose membrane, and the network of bony fibres and laminæ, which supports the marrow to the reticular membrane, which is mixed with and supports the adeps."

The modification of disease by the tissue affected is clearly pointed out in this paper; this has been admitted by all writers on pathology; and it contains some of the fundamental doctrines of inflammation, afterwards adopted by his brother John, particularly that inflammation always precedes suppuration, and that pus may be formed without any visible ulceration or breach in the solids of the parts. "The cellular membrane," he says, "is commonly supposed to be the seat of the abscess, or of suppuration. Indeed, considering the universality of this membrane, it can hardly be otherwise, for

the matter of an abscess must lie in the interstices of the parts; it cannot be contained within the fibre of a muscle, or of a tendon, for example; and therefore commonly it must, upon dissection, be found in a space which is naturally filled with the cellular membrane. Yet matter or pus is likewise found in the larger natural cavities of the body, in which there is no cellular membrane: in the cavity of the chest, for example. In these two different cases, I apprehend the pus or matter to be of a different nature; and that, in general, pus is of two different kinds: one is attended with a manifest breach in the solids, such as the matter of a common boil, which we shall for the future call abscess; the other is collected upon the internal surfaces of cavities when inflamed, and is not attended with any visible alteration or breach in the solids of the part, which we shall call inflammatory exudation. Pus of all kinds is therefore produced or preceded by inflammation. In an abscess the part is first in a state of inflammatory hardness and fulness; and generally in the centre of the swelling the vessels and fibres are broke and dissolved, and the fluid which is found in this ruptured part is called pus. We suppose this pus to be composed of the juices which were contained in the distended vessels, and of that part of the vessels themselves which was broke down, or melted by the suppuration. As the abscess ripens, the centre grows softer, from the accumulation of the fluids in the cavity of the abscess, and the surrounding inflammatory hardness goes off, both because more of the loaded vessels are reduced to pus, and because their rupture removes the obstruction to the circulation.

"I am inclined to think, that a very small quantity only of the vessels is destroyed in common abscess, be they ever so large; and thence we observe that there are hardly any traces left of large abscesses that heal up quickly. Indeed, when they have continued open a long time, as in ulcers, or when suppurations have been kept up artificially for a length of time, as in issues, the part heals up hollow, and the skin is immoveably fastened on the muscles and bone, as if all the cellular membrane had been destroyed. But even in these cases I suspect that the cellular membrane is rather condensed than destroyed, and what was naturally a loose spongy flesh is converted into a firm, compact, and unyielding substance.

"The pus of an abscess cannot diffuse itself along the cellular membrane in the same manner as extravasated blood or water, because the ruptured cavity in which the pus is contained is always encompassed by an inflammation, which hardens and unites all the fibres and laminae of the cellular membrane, and by that means renders it imper-

meable." He then minutely describes the manner in which abscesses make their way to the surfaces.

"Another kind of pus is that formed," he adds, "without any apparent breach or dissolution of the solids, and is therefore only a sort of inspissated serum, or inflammatory exudation. We occasionally meet with collections of this kind in all the natural internal cavities of the body. I have seen it in great quantity in the cavity of the abdomen, in that of the thorax or of the pleura, and in the pericardium, where there was no visible suppuration, ulceration, or dissolution of the solids on any part of the surface all round. This kind of pus is generally thinner than that of an abscess, and the containing surface is more or less covered with a glutinous concretion or slough, of the same colour as the fluid; in some parts adhering very loosely, in others so firmly, that it can hardly be rubbed off; but still the surface covered by these sloughs is without ulceration or loss of substance. This I have observed to be the case in all apbthons sloughs of the nose, mouth, throat, and trachea, that I have had occasion to examine attentively, both in young and old people. We every day meet with the same sort of pus by exudation from the more external surfaces of the body, which have no cuticular covering, or a very thin one, and which are naturally moist; when inflamed that moisture puts on the appearance of pus. Such discharges we see from the eyes, nose, throat, lungs, urethra, and vagina, and such I have seen collected upon the surface of the intestines as soon as they begin to inflame, when exposed to the air in an unsuccessful operation for the exomphalos.

"I imagine, too, that the pus of every sore, in the state of healing, or incarnation and cicatrization, is made up of juices only, not of a mixture of solids and fluids. The same thing is to be supposed of a blistered part, when in a healthy state. I presume we are to believe that the pus of a healthy wound is not discharged by exudation through the coats of the shooting vessels, but rather through their orifices; and, indeed, it seems not improbable, that every surface of the body, when inflamed to the degree of giving a purulent discharge, may be nearly in the state of a healing wound—they not only yield a similar discharge, but their surfaces, too, when in contact, unite, and their vessels shoot mutually into each other."

Vol. vi. Medical Observations and Inquiries, contains an Account by him of an Extraordinary Conformation in the Heart—History of an Obstinate Disease of the Heart.

1767.—Observations on the Bones, commonly supposed to be Elephants' Bones, which have been found near the river Ohio, in America.—*Phil. Trans.* vol. lviij.

In 1768, he was appointed, by the King, Professor of Anatomy to the Royal Academy of Arts. "This appointment opened a new field for his abilities, and he engaged in it as he did in every other pursuit of his life, with unabating zeal. He now adapted his anatomical knowledge to the objects of painting and sculpture, and the novelty and justness of his observations proved at once the readiness and intent of his genius."

In 1770, was published An Observation on the Insensibility of Tendons, by John Teekel, Surgeon: with an Introduction by Dr. Hunter.—*Med. Obs. and Inquiries*, vol. iv.

1770.—Appendix to the Preceding Article—Case of Retroversion of the Uterus, by W. Hunter, M.D. F.R.S.—*Med. Obs. and Inquiries*, vol. iv. p. 400.

In 1777, with Mr. Watson, he presented to the Royal Society a Short Account of the Illness of the late Dr. Maty, with the appearances on Dissection.—*Phil. Trans.* vol. lxvii.

His researches on the structure and diseases of articulating cartilages, the absorbent system, the ducts of the lacrymal gland, vas deferens, epididymis and tubuli of the testis, on the vessels of the pupillary membrane and crystalline capsule, adipose and cellular membrane, varicose aneurism, &c. would have entitled him, if he had contributed nothing else to human anatomy, to hold the most distinguished rank among the improvers of the science. But his work on the Anatomy of the Gravid Uterus and its Contents, published in 1775, is that on which he had bestowed the greatest labour, and which he foresaw would constitute through all future ages the most splendid monument to his fame. "The appearance of this work," says his biographer, "which had begun so early as the year 1751 (at which time ten of the thirty-four plates were completed), was retarded till the year 1775, only by the author's desire of sending it into the world with fewer imperfections. Something concerning the progress of this work, and of the zeal with which it was prosecuted, may be collected from different parts of his letter to Professor Monro, Senior, in the supplement to his Medical Commentaries.

"On the 11th of February," says he, "I was so fortunate as to meet with a gravid uterus, to which, from that time, all the hours have been dedicated which have been at my own disposal. I have been busy in injecting, preserving, and shewing it, and in superintending drawings and plaster casts of it. I have already made five very capital drawings from this subject. They, and some more, shall be engraved by the best masters as soon as possible, and then the whole shall be published. My first and original intention, you know, was to have published ten plates only; but, thinking the work im-

perfect, I waited patiently for more opportunities of adding supplemental figures. Sixteen plates were finished on this plan several years ago, but still I was dissatisfied with the work as being incomplete, and in spite of the importunity of many friends, I kept it from the public."

All the most important changes which take place in the gravid uterus during pregnancy have been accurately represented in these magnificent engravings. It contains a description and representation of two great discoveries which alone would have conferred immortality upon any anatomist. First, the outer membrane of the human ovum, called decidua, which is the great organ of circulation of maternal blood during the early months, by which the embryo is nourished and the function of respiration performed; and secondly the structure of the placenta and its connexions with the uterus. I shall take another opportunity of stating to you the evidence which completely satisfies my mind that the glory of this latter discovery belongs entirely to William Hunter.

In 1778, he published Reflections on the Section of the Symphysis Pubis.

On the Uncertainty of the Signs of Child Murder in the Case of Bastard Children, by the late William Hunter, M.D. F.R.S. 1783.—*Med. Obs. and Inquiries*, vol. vi. p. 266.

Three Cases of Mal-Conformation of the Heart. 1783.

The Anatomical Description of the Gravid Uterus and its Contents appeared twenty years after the Engravings.

As a proof of the respect and friendship he received from his patients I may quote the following letter from Lord Suffolk, which has never been published. W. Hunter's letter in reply will give you a far better idea of his real character than all that I have said.

Elford, February 18th, 1767.

SIR,—You forbid my addressing you as I meant to do, you restrain my gratitude from flowing in the only channel which is open to it at present. How am I to return the greatest obligations? You gave up everything to us; you resigned your own health to restore her's. Your heart felt for us, and now by a delicacy, a sentiment, a principle, unknown to the mean souls of these times, you rise superior to Reward. You do so, for the only adequate reward must proceed from yourself, independent of any body, I mean the consciousness of what you have done, that sweet reflection which shall soften the pangs even of such scenes as we have witnessed, alleviate all the cruel circumstances of disappointed merit, when success failed the kindest attentions, and the Almighty was not pleased (subluna-

vily speaking) to bless your care, or smile on the resigned fortitude of your patient; indeed, indeed, Hunter, she bore her illness in a manner to make man blush—but enough of that. My business is to beg of you, if reward is an irksome word, to let me substitute regard in its room, and when I come to London to entreat an opportunity of seeing you, and marking that regard. I will say no more of it now, save to insist, if hereafter in life, at any time, in any case, I may be so fortunate as to have it in my power to indulge my own wishes by being able to shew my gratitude to you, essentially as I ought and owe it, that you will do me the pleasure and favour, I will call it justice, freely to command it, for I shall always esteem myself *dum memor ipse mei*!

Your much obliged, though most unhappy friend and servant,

SUFFOLK.

Lady Andover, my sister, and little orphan, arrived safely here the day before yesterday. The child is very well, and has not suffered the least inconvenience from its journey. If she grows up in perfect health, if her beauty is complete, if her mind is as free from blemish as her body, and both are spotless, if she is truly virtuous, free from affectations, easy, unreserved, and with a word, a look, can keep fools at a distance, if in her happy composition, manly courage, and more than manly sense is tempered with female tenderness and endearment, if in every tried character and relation of life she stands unparalleled, the best of daughters, wives, and friends,—if above all she looks to the One Almighty God with humility and submission, religiously conscious that she is rendering herself most acceptable to him by doing her duty here in whatever station it pleases him to place her,—then will she turn out like her mother.

To the Earl of Suffolk.

My Lord,—An indispensable attendance prevented my returning my most sincere thanks, by the first post, for the very great honour which your lordship has done me. Be pleased, then, to accept the thanks of a grateful heart, which cannot express in words what it feels from reading your soothing letter. I am now by your lordship's kind sympathy as happy as I can be after taking such a share in so great a calamity; I feel an inclination to say a thousand things which I must suppress. I wish to talk upon a subject which you must forget. We will take it up in heaven. At this moment I fancy that I have a friend there who listens to my thoughts, and bids me to say to you, in a little time we shall be happy again; who bids me tell you to take care, for her sake, of yourself and of your child.

Allow me to love your child all the days of my life; she will be exactly what you describe and what you wish. Allow me sometimes to see her, that I may indulge a pleasing melancholy, and fancy that I am doing something very agreeable to heaven. It may be preparatory to some exalted enjoyment there. Allow me likewise to offer to your Lordship the best advice I can: as soon as possible, do a force to nature, and go into the busy world again; nothing but that, I think, can restore your peace of mind, and make you, what I am sure you wish to be, a blessing to mankind. May you yourself be blest, both for your own sake, and for loving so tenderly one so worthy of all your affection.—I am, my lord, with unalterable affection, your lordship's, Lady Andover's, your family's, most humble, and most devoted servant,

W. H.

Jermyn Street, February 24th, 1767.

As a lecturer, the character of William Hunter has thus been drawn by Dr. Baillie, one who was fully competent to appreciate his talents, being himself one of the most distinguished teachers of medicine who has ever appeared in London. "No one ever possessed more enthusiasm for the art, more persevering industry, more acuteness of investigation, more perspicuity of expression, or indeed a greater share of natural eloquence, than William Hunter. He excelled, very much, any lecturer whom I have ever heard, in the clearness of his arrangement, the aptness of his illustrations, and the elegance of his diction. He was, perhaps, the best teacher of anatomy that ever lived." As a teacher of midwifery he was not less distinguished, and rendered the greatest service to society by inculcating the propriety of trusting much, in all cases of labour, to the unassisted efforts of nature, and of employing instruments only where absolutely necessary. He rejected all parade, all wrangling, and subtlety, in his lectures, and did not aim so much at shewing his students what he knew, but laboured to show and describe as clearly as possible what they ought to learn. Sir Gilbert informed me, that the great secret of William Hunter's success as a public teacher was after all mainly to be attributed to the minute and profound knowledge he possessed of every subject which he discussed. In advanced life he continued to deliver lectures, though attended with pecuniary loss, because he considered it a duty which he owed to the public to do so. When he was about to close his earthly career, his mind still recurred to that occupation which he had regarded as the most important and delightful of his life. "I wish now," he said, "that I had strength to bear being carried into my

theatre, that I might tell my pupils how much comfort and happiness I feel." When on the brink of dissolution, he said, "if I had strength enough to hold a pen, I would write how easy and pleasant it is to die." His death occurred on the 30th of March, 1783.

Such was the peaceful and happy end of one whose talents through life had been devoted to the active service of mankind, and who had been constantly animated with the exalted sentiments thus expressed to the friend and guide of his early years:—

"As I have no children to absorb my attention, my affection to the public utility, whatever tends to make mankind happier, whatever raises them from ignorance and barbarity, and teaches them to enjoy the higher pleasures of life, I think should be the great objects of men who have been blessed with education. Judge, then, what pleasure I have in hearing of the good works going on with you. The flourishing state of your University gives me a very sincere pleasure indeed, and the more as the cause is so much in yourself. Tell me honestly, if you are not much happier to be so instrumental in doing so much good, and with so deserved a reputation for it, than you could possibly be by any pecuniary income that attention to worldly affairs could bring in. Go on, and in the remaining part of the short life of man, enjoy that longer life of fame which death will not be able to take away."

ON THE WHITE OR OPAQUE SERUM OF THE BLOOD*.

By ANDREW BUCHANAN, M.D.

Professor of the Institutes of Medicine in the
University of Glasgow.

"It is well known to all who have been in the habit of examining the characters of the blood, that the serum which separates from it, instead of being transparent and of a yellow colour as we usually find it, is sometimes opaque and turbid, white as if milk had been diffused through it, or otherwise discoloured. Such serum is usually spoken of as white or milky serum."

After an historical view of the observations made and opinions entertained upon the subject of milky serum, in which Haller, Tulp, Hewson, Hunter, Dr. Trail, Dr. Christison, Dr. Williams, and M. Lecanu, are referred to, Dr.

Buchanan proceeds to say: "My attention was particularly directed to this appearance of the serum in the year 1840, owing to the frequency with which it presented itself during some experiments I was then engaged in making on the constitution of the blood. I observed with Hunter, that it was of very common occurrence in the blood of young women, who desired to be bled, either because they were, or supposed themselves to be, pregnant; and whom, if no circumstances forbade, it was the custom to gratify in their request. Now, as these young women were for the most part strong and lusty, and therefore likely to take their food well, I was in doubt whether to ascribe the whiteness of the serum to their peculiar state of body, or to the food which they had probably taken not long before. To resolve these doubts, the most direct mode was to have a person in sound health bled at different periods after a full meal, so as to observe the effects of digestion upon the blood. Accordingly, a strong healthy young man, to whom a good dinner was an equivalent for the loss of a few ounces of blood, was easily prevailed upon to submit to the following regimen and treatment. He had no breakfast, and at four o'clock had for dinner one pound of beef-steak, half-a-pound of bread, sixteen liquid ounces of brown soup, and half-a-bottle of porter. Three ounces of blood were then taken from a vein in the arm at three different periods; the first time, half an hour after the meal; the second time, an hour and forty minutes after it; and the last time, next morning at eight o'clock, or sixteen hours after the meal, no food having been taken in the interval. The blood as it issued from the vein had the usual appearance, and the serum which separated from it was about the same in quantity each time. The first time the serum was whitish and turbid; the second time it was like whey; while the third time it was perfectly limpid. The crassamentum on the two first occasions exhibited nothing peculiar, while on the last it was covered with a transparent fibrinous crust beautifully interspersed with white dots; which led the medical friend, who assisted me in these investigations, to compare it to a precious stone.

* From the Transactions of the Glasgow Philosophical Society, March 1844.

As it might be supposed that this

young man's blood was white before he took dinner, the two following trials were made to obviate that objection.

A vigorous man of about 35 years of age, after fasting 19 hours, had for dinner, twenty ounces of beef-steak, sixteen liquid ounces of brown soup, and eight ounces of bread. He was bled immediately before his meal, and three times after it, two ounces of blood being taken away each time. The serum obtained from the first bleeding before the meal was perfectly limpid; the serum from the second bleeding, three hours and fifteen minutes after the meal, was turbid; the serum from the third bleeding, eight hours and fifteen minutes after the meal, was still thicker; while that from the last bleeding, eighteen hours after the meal, was again quite limpid, although some supper had been eaten in the interval.

The young man first mentioned, after fasting eighteen hours, dined upon sixteen ounces of brown soup, four ounces of bread, eight ounces of potatoes, twenty ounces of beef-steak, and sixteen ounces of London porter, and fasted eighteen hours after the meal. He had blood taken from his arm four times to the extent of two ounces each time. The serum of the blood first taken, immediately before the meal, was of an amber yellow, and quite transparent; the serum from the second bleeding, two hours and ten minutes after the meal, was turbid; the serum from the third bleeding, eight hours after the meal, was turbid; the serum from the third bleeding, eight hours after the meal, was exactly of the colour of water gruel and quite opaque; the serum of the blood last taken, eighteen hours after the meal, was still turbid, its limpidity not having been, as after his usual fare, restored by an eighteen-hours' fast.

In neither of the two last cases did the blood, as it issued from the arm, present white streaks or any thing else unusual. The crassamentum of the blood drawn before the meal was in both cases of the usual red colour on the surface, as also that drawn first after the meal in the last case; but in all the other instances it exhibited the same *pellucid fibrinous crust* already described, although not dotted in the same remarkable way. We can scarcely avoid the conclusion that this pellucid crust is connected with finished digestion,

when we reflect that out of nine bleedings practised within eighteen hours after a very full meal, this crust was observed on every occasion, if we except those in which the blood was drawn within three hours and a quarter of the period of taking the meal.

These observations, the accuracy of which I have since had opportunities of confirming, appear to me to leave no doubt as to the origin of the white colour of the serum of the blood. When a healthy man is bled fasting, his blood yields serum of a transparent yellow colour, like light Sherry wine, varying in the depth of the yellow tint, but always perfectly clear. In about half an hour after taking food, the serum becomes turbid, the discolouration increases during several hours till it attains its maximum, after which the serum becomes again gradually clearer, till its limpidity is perfectly restored. The period at which the discolouration is greatest, and the length of time during which it continues, must depend mainly on the quantity of food taken, but also in some degree on its quality, as some kinds of food are digested more readily than others. It may, however, be stated, so far as the observations I have made enable me to judge, that after a full meal of different kinds of food, the discolouration is greatest about six or eight hours after the repast, and that probably somewhat more than an equal period elapses before the serum regains its limpidity. The differences of colour, which are considerable, probably depend on the different substances digested: and it is interesting in this point of view to remark, that the colour varies in the successive bleedings after the same meal, as if the differentialimentary principles produced different kinds of discolouration, and entered the blood-vessels at different periods.

If these views be correct, it is clear that a milky state of the serum of the blood is a phenomenon of the healthy body, and cannot in itself be regarded as a symptom of disease. There are, nevertheless, certain circumstances in which this appearance may serve to indicate the existence of disease, as when it continues during a longer period than according to the laws of health it ought to do. A case is mentioned above, in which, after eighteen hours fasting, the serum of

the blood was still loaded with white particles. The only inference that could be drawn from this fact, was, that the individual had taken a more than usually large quantity of food, and that the digestion in the blood-vessels was protracted in proportion. Perhaps it would not be warrantable to deduce any other inference, even were the milkiness to continue for twenty-four or thirty-six hours after a full meal. But when this milkiness continues for several days, although the appetite is gone and no fresh supply of food taken, it then becomes probable that the digestion in the blood-vessels is no longer going on, as in the healthy state; being, like all other functions of the body, subject to retardation and derangement from the condition of the organs by which it is performed. Thus Morgagni found the serum white in the blood of two patients labouring under fevers; of which he describes the one as malignant and attended with much danger, and the other as verging to malignity. In the former, the whiteness was observed in blood taken by the three last of four venesections which were required; and in the latter, in blood taken on the third, and again on the fifth day of the disease.*

I conclude with a few remarks upon the physical and chemical characters of white or milky serum.

The colour of the serum is generally a milk-white; sometimes a cream-yellow, or a yellowish-brown; when the liquid bears a striking resemblance to thin oatmeal gruel. There is sometimes little discolouration, the serum merely losing its limpidity, and changing its hue so as to resemble a weak syrup made of coarse sugar.

In all the instances in which I have examined the liquid with the microscope, it showed a great number of solid granules mechanically suspended in it. They are less in size than the corpuscles of the blood, generally of irregular shape, but often spherical, and having the appearance of a nucleus in the centre, most probably from the refraction of light. These particles were as abundant in the syrup-like serum as in the more opaque varieties; but they were less regular in shape, and seemed to be themselves translucent.

It sometimes happens, as has been

observed both by Hewson and Hunter, that after the liquid has stood for some time, the white particles separate from it, and rise to the surface like cream. Hewson attempted to effect this separation by churning the serum, but without success. I accidentally hit upon a process by which the object is readily effected. It consists in saturating the liquid with common salt, which so much augments its specific gravity, that the opaque particles becoming relatively lighter, rise to the surface, either immediately, or soon after. This process has the further advantage of preserving the liquid.

The white matter separated by the filter is insoluble in water, and is thus easily purified from the salt with which it is mixed on the filtering paper, by steeping the latter in water, and then cautiously drawing off the water holding the salt in solution. Thus obtained it has the form of a fine white powder, which in two specimens in my possession bears a very close resemblance to wheaten flour. On holding a little of it in the flame of a spirit lamp upon a platinum spatula, it was immediately charred, and burned away almost completely. Dr. R. D. Thomson was kind enough to examine a specimen of it for me, but it was too minute in quantity to admit of a satisfactory analysis. He found it quite insoluble in ether and alcohol, while it dissolved in caustic potash. On boiling it in a solution of sugar of lead, it gave traces of black sulphuret. He concluded, therefore, that it contained no fixed oil, and consisted most probably of a *proteine compound*, like albumen or fibrin.

Postscript.—After the meeting of the Society on the evening of the 13th inst., it occurred to me as possible that the starch might be converted by the organs of digestion into sugar, and be absorbed in that form into the blood. I accordingly procured some yeast next day, and treated with it the serum of the blood, which had been taken three hours after the meal, proceeding in the same way in which I am in the habit of examining diabetic urine. Fermentation ensued, and continued about forty-eight hours, the heat not having been regularly maintained. The serum from the blood of another individual who had used the same diet, but more sparingly, was treated in the same manner, when the same result ensued,

* Morg. Epist. 49, Art. 22.

only the gas was somewhat more abundant. But what struck me as more remarkable still, was, that the serum of the blood which had been taken from both these individuals after fasting, likewise fermented; although the quantity of gas obtained was much less than in the former instances. I found that the largest quantity of gas obtained in these experiments was about equal to that obtained by means of the same apparatus, from a solution of sugar in water, containing five grains to the ounce. Should farther observations confirm the idea here suggested of the existence of sugar in the blood as a normal product, it is obvious that a corresponding modification must be made of the prevailing theories of diabetes, according to which the production of sugar is regarded as the essential derangement of action in which that disease consists.

[Dr. Buchanan's observations go to prove that the ordinary kind of white serum is caused by the presence of chylous matter in the blood; and this conclusion agrees with the researches of Mr. Gulliver, who states that he often observed a milky condition of the serum in young and perfectly healthy animals during digestion, both in the arterial and venous blood (Appendix to Gerber's Anatomy, p. 21 and 22). He also found the milky matter to be, both in its chemical and microscopical character, identical with the *molecular base* of the chyle, which there is every reason to believe is of a fatty nature (Gerber's Anatomy, Note, page 56, and Appendix, p. 23). It is true that a few globules about $\frac{1}{100000}$ of an inch in diameter existed in the milky matter; but the mass of it was composed of very minute molecules, which may be assumed as the characteristic element, as the ground or base of the chyle.

And thus far it is easy to reconcile these facts with the facts announced by Hewson; who states that the milky matter of blood is composed of exceedingly minute globules, comparable to the smallest globules of milk, spherical in shape, regular or equal sized, and only just visible under a lens of $\frac{1}{23}$ of an inch focus, (Exp. Inquiries, part I, third edition, page 141, et seq.) a description agreeing remarkably well with Mr. Gulliver's account of the mo-

lecular base of the chyle, especially when we recollect that Hewson, like Gulliver, considered the milky matter of blood to be of a fatty nature (loc. cit., p. 149).

Thus far Hewson's facts seem to be incontrovertible. Not so, however, the explanation which he has given of these facts. He did not think it probable that the milky serum was caused by unassimilated chyle, because he found the appearance in persons of bad appetite, who were subject to vomiting; and finding this appearance in the blood of persons of plethoric habit, inclined to corpulency, with a stoppage of a natural evacuation, he conjectured that the milky serum was caused by reabsorbed fat (loc. cit., p. 150). Yet he adds in a note, that he would not conclude that the chyle does not in the human subject occasionally colour the serum; and if, like Dr. Buchanan and Mr. Gulliver, Hewson had carefully observed the blood of healthy brutes and of man during digestion, it is probable that his deduction from the facts would have been similar to the results above given.

But, after all, it is not improbable that there are two, if not more, kinds of milky serum; one dependent on an admixture of chylous matter, and another connected with causes of a more obscure nature occurring in disease. Of the latter sort, the white serum observed by Morgagni in malignant fever, and cited by Dr. Buchanan (p. 7), may be regarded as an example.

The subject, therefore, requires further research; and it is to be hoped that this will be undertaken by an observer like Dr. Buchanan.—ED. GAZ.]

ACESIUS*:

A SURVEY OF THE ETHICAL RELATIONS OF
MEDICINE.

By C. F. H. MARX, M.D. &c.

(For the London Medical Gazette.)

[OUR readers were, we believe, unanimous in their approbation of the elegant essay, on the Decrease of Disease, by the accomplished Professor of Göttingen, which appeared in the pages of our volume just concluded. We have reason to think that the series of short papers, of which the first now appears,

* *Acēsios*, the Healer, from *acēopai*, medeor, and *acēsīs*, medicamentum.—ED. GAZ.

from the same admirable pen, that only leaves traces of goodness and truth, of wisdom and piety, where it has been, will prove no less acceptable to the patrons of the LONDON MEDICAL GAZETTE. We have therefore great pleasure in presenting them with the Preface, and first Letter, of Dr. Marx's *AKeios*, this day; promising, in the name of the author, short biographical notices of the several personages to whom his letters are addressed, by and by.—ED. GAZ.]

PREFACE.

AKESIUS (*AKeios*), or the Healer, was one of the names by which the Greeks designated the Divinity whom the Egyptians entitled Harpokrates. Born at the winter solstice, he was emblematical of the weakness of the sun at mid-winter; but he also typified the hope of renovated life with the return of the god of day to the superior signs. He was therefore an apt emblem of the sick man's feebleness coupled with the prospect of his recovery. Harpokrates was represented with his finger upon his lips, significant of the holy reserve which the initiated into his mysteries were held as pledged to observe.—(Sprengel, Hist. of Medicine, 3d edit. i. p. 72.)

I attach myself in the following pages to the first consolatory and hope-bringing symbol especially. My purpose is to pass in earnest review some of the most essential and momentous topics of the healing art. Secrets, mysteries, however, if any such there are or ought to be in medicine, I mean not to touch upon. I do not treat of methods of cure, nor yet of curative means; but of things which lie open to every eye, which are engraven in every heart, and which are most intimately connected with the very soul of the medical profession and of medical practice—the ethical, the moral, the individually reputable—these are the subjects that form my theme.

That I have thrown my thoughts into the shape of letters happened from this; that I naturally had an individual in my eye,—some master in one department or another of our art,—whose character, purposes, fate in life, or autobiography, seemed to me particularly to illustrate the subject that lay before me. To him, almost naturally, I addressed myself. It will be seen that

he with whom I thus hold converse is never of the present day; he is often of an age that has long gone by. But I have in this way gained ample scope for the selection of my correspondents, and have felt myself perfectly free to write as my thoughts prompted me; and I think that he who is not indisposed to the purpose which I have at heart in these letters, and who approves of their tendency, will excuse me the fancy which has led me out of the busy present, to address myself to the spirits of departed greatness.

C. F. H. MARX.

Göttingen, May 16, 1844.

TO STIEGLITZ,—

Ever since the 30th of October, 1840, when you said farewell to your friends upon earth, not my letter-paper but my days have been surrounded with a mourning rim.

With the unexpected news of your decease, I felt that the death of my friend had made a rent in my heart, that the departure of a great man was a kind of flaw in my nature.

Nearly four years have fled under impressions of various kinds since then; but my spirit is still shaken as if I had lost you only yesterday;—the magnitude of the loss has only become clearer to my mind.

To bring the long years in which I lived with you in such familiar interchange of thought and sentiment more closely before me, and to hold a kind of resurrection-festival to your love and honour, I once began to rear a monument of tender recollection to your memory; but however excellent the material, the chisel in my trembling hand refused the task.

And, to speak truth, my poor presentment is not required: for to contemporaries you were a lofty model, and your works remain to posterity. To me, nevertheless, you ever present yourself as a beloved father or instructor putting forth his hands to bless.—Wherefore is my heart softened more than wont to-day? wherefore do I invoke your name more fervently now than usual? Because I am about to speak of men who consecrated their thoughts and their energies in life to pure humanity. With such a purpose before me, shade of Stieglitz! you will not take it amiss that I think first of you.

You possessed two qualities which are more rarely found united in the same practitioner than is commonly supposed, — genius and experience. Through this it was, unquestionably, that you possessed that admirable tact in prognosis; for Euripides, in his *Helena*, calls the union just alluded to the surest soothsayer; or as our own national poet*, speaking of Columbus, has it, that the anticipated land, had it not yet been, must needs have risen from the bed of the ocean to greet him on his westward course—in such intimate relationship does nature stand with genius; even so would you have created theoretical medicine had you not found it already extant.

But it is not my present purpose to speak of you in this direction; I would here and at this time only proclaim and indicate what prolific germs your wide-spread activity sowed in the moral soil.

The leading feature in your character, the love of truth, you fostered as philosopher by severe criticism, as man by intent and deed. With your inherent abhorrence of falsehood, of a lie in every shape, you had the boldness, where necessary, to call things by their right names, and, without regard to the assent or countenance of others, to give utterance to your intimate convictions.

As in the search after truth you always chose for yourself the shortest way betwixt the plan and its performance, so did you exercise towards others the difficult but indispensable duty of frequently saying No.

In your work *On the Conduct of the Physician at the Bedside*, you showed with as much clearness as kindness that the patient only profits by the consultation when his attendants agree in their views of the essential nature of his case, and are well inclined towards one another. The engraving which forms the frontispiece of Fritze's *Annals*, after Chodowiecki's picture, in which the sick man looks out from his bed with more than significance in his expression upon the three descendants of the Asklepiades who are intent upon their consultation, you always spoke of as true to nature; and you undoubtedly knew the epitaph on Hadrian's monument: *Turba medicorum perdidit Cæsarem*.

With the same untiring industry wherewith you strove to obtain independent views of all phenomena, and to gather arguments in support of your opinions, with like gentleness of spirit were you disposed to listen to the views and arguments of others. Your indulgence in judging of others, your excuses for all imperfections, infused respect and admiration, if they did not always bestow the ability to imitate you.

As there is no code of laws for the medical practitioner, you pardoned mistakes, but not readily injurious proceedings. Your own persuasion that the tables of the law which man received originally from God were occupied by but few commandments, you never forced upon others. You desired that the acts of the medical practitioner might be viewed as moral transactions, and rather to be prized in the purpose than in the effect.

As you made it a fundamental rule of action to depart no more in the affairs of life than of art, from the highest motives, so did you with increasing years withdraw yourself greatly from practice—a course that was not understood and was even falsely construed by many.

You were desirous, however, of leaving to younger talent a freer stage for the development of its capacities, and to dedicate the more unembarrassed hours of leisure thus secured to study and to writing. And I have myself had ample opportunity of knowing with what care and comprehensiveness you perused and criticised the works of strangers.

You still met the new proposals, the bright anticipations, of enthusiastic youth, with heartiness; into the minds of your younger brethren you poured sage advice, and set before them in attractive lights the goal to be attained. Each word you spoke sounded like a lesson, each lesson like an intimate conversation—indelibly did it sink into the soul; pregnant with future fruits did it there take root and grow.

Science and the land you served will ever hold your memory in honour; with me it will be cherished to my latest breath.

* Schiller.

RECORD OF CASES.

By THOMAS MAYO, M.D. F.R.S.

Physician to the Infirmary of St. Marylebone.

[Continued from p. 438 of Vol. xxxiv.]

The following cases may have some interest as illustrating the complication of thoracic with cerebral congestion, which was the subject of a former article contributed by me to the *Gazette*.*

G. Sharpe, aged 42 years, was admitted into the Marylebone Infirmary, April 17, 1844. He was well and rather strongly made, his hair dark, his complexion pale. His manner was confused and nervous, his articulation imperfect and uncertain: he seemed constantly drowsy; his only complaint was of pain in the head. The pulse small; there was some slight cough. He was at first examined in this latter relation only under the clavicles, and under both his breathing was excited, but perfectly vesicular. He could give no clear account of his previous illness.

April 19th.—*Sumat. Hydrarg. Chlor. gr. iv. statim. Misturæ Ætheris, c. Scillâ, ʒiiss. 6tis.* having been ordered by the resident physician on his coming in.

22d.—Pain in the head abated; in other respects he is unaltered. From this day to the 28th symptoms remained stationary. The above draughts were continued, and the action of the bowels maintained by *Pil. Ext. Colocynth. Co.* On the 29th the face became highly flushed, and the breathing quickened. The pulse was still of small calibre, and the action of the heart scarcely audible. The tongue had become brown and rather dry. He did not complain of any pain or uneasiness, but was as inattentive, unobservant, and inarticulate, as usual.

I directed *Cucurb. Cruentæ inter Scapulas ad ʒviij.; Misturæ Tragacanth. ʒiiss.; Potassæ Bicarbon. ʒj. 8vis.; Hydrarg. Chlorid. gr. ij. 6tis.*

May 1st.—To-day he is much more articulate, observant, and cheerful, and describes his head as greatly relieved. Some bloody sputa, like currant-jelly, are taking place. I observe that the right lungs posteriorly are duller than the left, and the breathing less vesicular; large crepitation in both. From

this day to the 7th of June large crepitation was observable posteriorly in the lower portions of both lungs, with deficient vesicularity and some dulness on percussion, at first principally on the right side, then on the left. There was little dyspnoea, and no pain, except, on the 22d of May, a sharp accession of pain under the left mamma, with deficient respiratory murmur in the neighbouring lung, and increased sound of the heart. This pain was easily relieved by six leeches. The pulse ranged generally at about 84. The tongue was coated in the centre. During this period of time a free expectoration of thick lumps of dark blood continued, and the visage became very anæmious. Meanwhile the mind became clear and sound, the drowsiness ceased, the articulation righted itself. Up to the 7th of June, the last-mentioned treatment had been continued, the calomel being reduced to one dose daily from the 17th of May. It was then discontinued, the mouth being affected. On the 14th of June, I find in my notes that the pallor had become extreme, but the sputa were then nearly free from blood, and slightly purulent. On the 22d, all appearance of blood had ceased. On the 3d of June, I should observe that a large blister had been applied inter scapulas with marked good effect.

The patient is still in the Infirmary (Sept. 17th), somewhat anæmious and weak, but free from complaint.

One most instructive part of this case I take to be the natural and unimpeded course which it followed during its earlier period; though in saying this I must myself plead guilty to some tardiness in discovering its nature, and controlling its progress.

As little was known of the case which I next adduce as of the above one, when it was received into the Infirmary, the 22d of February, 1844. It appeared, however, that the patient, Richard Woolley, a middle-aged man, had been intemperate. He had a sharp, excited, over-ready way of expressing himself and answering questions; his perceptions were clear; his mind was travelling from topic to topic with morbid rapidity, but not without a rational connection. He was restless in bed, and would throw about his own clothes and those of persons about him, so that it became necessary to put on

* Vol. xxxiv. p. 15.

the strait-waistcoat for a 'short time. His tongue or his hand were protruded with morbid readiness if either were asked for. He did not complain of pain. Leeches had been applied to him before I saw him.

On the 23d, I found him as above, with a tongue dry and red down the middle. His urine was reported to be sufficient in quantity; he had obtained no sleep since he came in; his pulse was small and low.

Sumat. Hyd. Chlorid. gr. ij. bis quotidie;
Liquor. Opii Sedativ. ℥ xxvi.; Mistura
Camphora Vespere, 3tis horis repetend.
donec dormiat. Strong beef-tea was
allowed.

On the 24th I found a small weak pulse; no sleep had been obtained.

I now was satisfied that the case must be treated entirely as delirium tremens, and ordered—

Porter, 1 pint statim.; Opii, gr. iss.;
Camphoræ, gr. ij. secundis horis donec
dormiat.

25th, meridiæ.—I found that after two of the above pills he had obtained much good sleep, but there was no improvement in any other symptom. The same principle of treatment was continued.

26th.—Much worse; struggling violently in the waistcoat, which had been unavoidably resumed. No sleep last night.

Pil. ij. supra præscripti statim, et 4tis horis donec dormiat.

But little effect. Death took place on the 27th. During the last two days brandy and some port wine had been given.

Autopsy.

Cranium: convolutions flattened. Tunica arachnoidea opaque in many places, and remarkably dry. Pia mater not much congested; substance of brain firm. Ventricles highly distended with fluid. Tunica arachnoidea, where it invests the lateral ventricles, opaque and rough.

Thorax: heart normal, but rather small; edges of aortic valves somewhat thickened; vegetations round the free edges of the mitral valves. *Lungs everywhere highly engorged, and full of miliary tubercles.*

Other viscera healthy.

The character impressed upon the

cerebral symptoms of this case by the intemperate habit of the patient, was that of delirium tremens. Meanwhile it may safely be affirmed that the tubercular and congested condition of the lungs, if it did not *cause* these symptoms, must have largely contributed both to their magnitude and to the inefficacy of the treatment adopted under them.

The vagueness of such terms as delirium tremens is to be regretted; but, in the present stage of our science, is not always avoidable. The above case is valuable as illustrating the superiority of that pathological diagnosis which is founded in structure, when it can be attained. Meanwhile it is to be regretted that our nosological systems are not so constructed as to distinguish those heads of disease which have this basis, from those which have not.

[To be continued.]

CASE OF HYDATID TUMOR OF THE LIVER; WITH REMARKS.

By SOMERVILLE SCOTT ALISON, M.D. Edin.

Licentiate of the Royal College of Physicians
of London, and Physician to the
Northern Dispensary.

(For the *London Medical Gazette*.)

MR. N., aged 75, native of Scotland, of middle stature, broad and well-formed, of melancholic temperament and sallow complexion, of very regular habits, sober and careful in his mode of life, was delicate and ailing from infancy. For many years he had suffered various dyspeptic symptoms. Some years ago he was supposed to be affected with gall-stones, but it does not appear that any were ever seen. About five years ago he was the subject of an acute attack of pneumonia, which it appears was overlooked for some days; soon after this, symptoms of diseased heart manifested themselves. Last autumn he suffered several severe paroxysms of pain, commencing in the back, running up to the face and into the teeth, and rushing down into the arms. The pain was accompanied with hurried respiration and copious sweating. The attack would come on instantaneously, and in the course of an hour or two pass en-

tirely away. The patient was in Edinburgh at that time, and was seen by different practitioners, but it does not appear that the nature of the paroxysm was understood. My respected friend Dr. Alison, of Edinburgh, at a subsequent period saw the patient, and regarded the case as one of hypertrophy of the heart, depending on disease of the aortic valves, with the usual complications of obstructed hepatic and cerebral circulation.

The patient came to town in spring, and placed himself under my care. He complained of much constant uneasiness in the abdomen, and of occasional pain over the region of the umbilicus. The liver was much enlarged, and descended much below the false ribs of right side; it occupied the whole umbilical region, and the edge of the left lobe could be felt extending along to the immediate vicinity of the left ilium. The epigastric region, together with the greater part of the left hypochondrium, was occupied by the enlarged viscus. The surface was even, except at the usual site of the fundus of the gall-bladder; at that point the liver projected, and gave the sensation of a tumor. Pressure did not produce much increase of uneasiness; percussion gave dull sounds, and a marked sensation of fluctuation over the point where the tumor was felt. When the fingers were dipped, as it were, into the liver, the fluctuation was most distinct. Little fluctuation was felt in any other part of the abdomen. The appetite was indifferent, but food did not create pain. The stools were bilious, frequently almost black, but sometimes they were pale. The bowels were inclined to be constipated, and required the occasional use of laxative medicine. Urine plentiful, alkaline, and deposited copious sediment of lithate of ammonia. The situs of heart preternaturally large, extending from 3d rib to 7th, and from the edge of sternum to a point an inch beyond the left nipple. The motion of heart was heaving and prolonged; the impulse much augmented. The first and second sounds were rough, but no bellows sound was heard. The pulse was not small, was hard, slightly intermittent, and 80 per minute. The veins of neck were distended; the external jugulars stood out in relief, and were nearly half an inch in diameter. There was dyspnoea to a

slight extent; he coughed occasionally, and expectorated mucus. The patient usually suffered from a degree of oppression in the head; in the mornings, just before rising, he experienced considerable headache, which would pass off during the morning. The pupils were considerably dilated.

June 6th.—The patient experiences much pain in abdomen: the abdomen is enlarging rapidly; fluctuation is felt in the right hypochondriac region; there is considerable œdema of the feet; pulse 110 and strong; tongue much furred.

Sumat. statim haustum c. Sulph. Magnesie, Tart. Potassæ, Tinct. Digitalis, et Tinct. Hyosc. confectum. Capiat necnon, Pilul. c. Scilla, Chloridi Hydr. et Ext. Colocynth. C. præparatum, mane et nocte.

7th.—Is still suffering much uneasiness in abdomen.

Detrahantur uncie octo sanguinis a dextro hypochondrio cucurbitulis cruentis.

8th.—Is much exhausted; skin covered with copious drenching sweat; much drowsiness; pulse 110, weak and irregular; complains of uneasiness in side.

9th.—Is much relieved.

15th.—Has continued tolerably easy, but has occasionally suffered pain in abdomen, which the patient likens to spasm. The veins of neck are less distended than before; the external jugular veins collapse at every inspiration, and become distended at every expiration, the distension beginning from below, and gradually ascending: the appearance is such as might be expected from inflating the vessel with air from below upwards, and is calculated to give the erroneous idea that the blood is slowly regurgitated into the vein from the thorax.

19th.—Has vomited much acid fluid.

23d.—Tongue and lips have within the last few days been covered with aphthæ.

29th.—Is much weaker; complains of pain in epigastrium; mucous membrane of mouth free of aphthæ, but red and irritable.

July 14th.—Has been very weak and uncomfortable; pulse very irregular; skin hot; tongue red; feet œdematous. Temperature of hand 93°.

16th.—Is very feeble; œdema of feet much increased. Urine red: speci-

fic gravity 1014; turmeric paper is rendered brown, nitric acid causes effervescence, and precipitates lithic acid; liq. ammoniæ gives no precipitate, and heat renders clear.

Aug. 2d.—Had been somewhat relieved the last few days, but was suddenly seized to-day with very severe pain in the abdomen around the umbilicus, and over the seat of the projecting part of liver. The respiration was hurried; the patient bent forward, and groaned. A dose of hydrochlorate of morphia, with sulphur. æther., was given, and in a few hours he was much relieved.

3d.—Has had a little sleep, and feels better; has had several stools of an ash colour; no gall-stones could be found.

5th.—Is sinking; large crepitation is heard all over chest; much yellow expectoration is coughed up. Pulse very feeble, but less intermittent than for some weeks.

11th.—Pulse very intermittent.

12th.—In endeavouring to sit up in bed to expectorate, the patient died this morning.

The treatment throughout did not aim at more than the palliation of the patient's sufferings, and the support of his strength. Three weeks before the death of the patient, Dr. Bright saw him along with me.

Sixteen hours after death the body was examined. Thorax: the pleura-costalis was intimately connected, by old adhesions, with the pleura-pulmonalis on both sides, but most extensively on the left side; there was no effusion in the pleural cavity. The lungs did not collapse on opening the thorax, and were emphysematous, particularly in the upper lobes. The upper lobes were darker than usual. There were several condensed hardened spots of a darkish hue, and within these spots were found melanotic tubercles, hard and resistant to the knife. The hardened parts had been the seat of inflammation. The pericardium was healthy, and contained the usual amount of serous fluid. The heart was greatly enlarged, and weighed nearly two pounds. The walls of left ventricle were much augmented; the cavity was not increased, and was filled with coagulated blood. The mitral and tricuspid valves were healthy, but the semilunar valves of the aorta were stiff

and almost immoveable, in consequence of much bony deposit. The margins of the valves were hard, and resistant to the touch. The aorta itself was free of disease.

Abdomen.—On laying open the abdomen, about ten ounces of serous fluid were found, the specific gravity of which was 1017. The omentum and stomach were covered over by the greatly enlarged liver. The colon was much displaced, and prevented rising from the caput cæcum to form its arch; it coursed across the abdomen, forming a concavity in the first part of its course. The cæcum was in its usual place, but greatly distended with flatus. The liver was greatly enlarged, and occupied almost all the upper part of the abdomen. The right lobe was of the colour of parchment, hard and globular; the left lobe presented the usual appearance of liver. The right lobe fluctuated, was tight, and felt greatly distended. The liver weighed nearly ten pounds, measured from the right extremity to the left 13 inches, and from the superior to the inferior margin at right lobe 7 inches. The left lobe was healthy; the peritoneal covering of the right lobe was thickened and rough; it was not adherent to the surrounding parts. The right lobe formed a globe; upon incising, vast numbers of hydatids, swimming in colourless glairy fluid, escaped, varying in size from a garden pea to a pigeon's egg: some of the larger hydatids were collapsed. Many hundred hydatids were found, and they, together with the fluid in which they floated, might have filled three pint bottles.

The right lobe of liver after being emptied of its contents proved to be perfectly hollow; the walls of the bladder, for such it was, were in no part above one-third of an inch in thickness; in the greater part of this extent, the walls did not exceed above a few lines in thickness: the anterior part did not reach above half a line: a long slip was preserved, and is now in my possession, the thickness of which on the whole is not more than half a line—about the thickness of a good kid glove. Very little of the proper liver structure was to be seen, and only in those few parts where the thickness reached a third of an inch. The liver structure was pale and unusually flaccid. The exterior of the cyst was rough,

uneven, of a greyish colour, not vascular. The solid remains of the right lobe including the cyst could not exceed four ounces in weight, but they were not put into the balance.

The gall bladder was empty, and diminished in size. The peritoneal covering of the abdominal parietes was healthy. The head was not examined.

The foregoing case affords many points for useful reflection. From the history of the case it is reasonable to conclude that hydatids had been present for many years in the liver. It does not seem at all improbable that the dyspeptic and bilious symptoms which the patient suffered ten or twenty years ago, arose from the hydatid tumor. It is more than probable that the paroxysms of pain which the patient endured several years since, and which were referred to the impaction of gall stones in the biliary ducts, depended upon the presence of hydatids in the liver, for it appears that no gall stones were discovered, although diligent search was made for them by a medical practitioner. This extended duration of the disease is of value in practice, as it warns us against rash or violent attempts at relief when the symptoms are not of a very pressing nature. Nor is the continuance of life under such circumstances calculated to cause surprise, when it is borne in mind that the hydatid tumor is less connected with malignant action than with a cachectic condition of body, and that it causes death rather by its mechanical operation on the neighbouring parts, than by any morbid action of its own.

The current opinion that the hydatid formation both in man and in the lower animals is connected with a cachectic condition of the body, is confirmed by the history of this case. We learn that the patient had been delicate from infancy; that he had never enjoyed robust health; that after attaining to manhood, through a sickly youth, he was afflicted from time to time with bilious and dyspeptic disorders throughout a long life. Perhaps the presence of the melanotic tubercles in the upper lobes of the lungs may be regarded as a further proof of the cachectic condition in this patient. For my own part, I regard them as evidence of such a condition, rather than of a malignant diathesis.

It is important to know that the

patient was exposed to those forces which are known to favour the formation and growth of the cachectic condition. Having spent his infancy and early youth in Scotland, he was reared chiefly upon vegetable and farinaceous diet: no doubt the oatmeal porridge, which enters so largely, and therefore so prejudicially, into the diet of the humbler classes of Scotchmen, assisted in the formation of the cachectic condition. In early manhood he came to London, and for about half a century, struggling with indifferent health, he, like many of his countrymen in this metropolis, led a life of unceasing toil, scarcely relaxing to partake of the necessaries of life, and labouring on, after having, in the capacity of a workman, realized a sum with which many master-tradesmen would rejoice to retire from business.

The almost total destruction of the right lobe of the liver is a remarkable feature in this case. The writer is not aware that any case is recorded in which so large a portion of the liver was destroyed. He has not met with any recorded cases in which the right lobe was, as in this case, totally converted into a bag or cyst, but his countryman, the late Dr. Matthew Baillie, has given the history of a hydatid tumor of the kidney, the kidney being converted into a "bag" containing three pints of hydatids. No obvious poisoning influence from imperfect depuration of the blood in the liver was present, and it appears that the duties of the annihilated right lobe of the liver had been effectually performed by the other parts. It is, however, possible that the depurating process might not be *perfectly* performed, and that the dark condition of the upper lobes of the lungs, and the melanotic tubercles formed there, were connected with the morbid condition of the biliary organ. The obstructed circulation consequent upon the disease of the heart is sufficient to account for the oppression and pain of head which the patient frequently suffered, and renders it unnecessary to refer these symptoms to an impure condition of the blood. That the biliary secretion was formed in not very deficient quantity is proved by the colour of the stools, which were sometimes dark, and though sometimes light, were never destitute of bile.

I have mentioned in my report that

the paroxysms of pain which the patient frequently suffered were not unlike the paroxysms experienced during the progress through, or impaction in, of gall-stones in the biliary ducts. This resemblance has, I perceive, been pointed out by other writers. Dr. Kerr, in his able article on Hydatids, in the Cyclopædia of Medicine, says:—Occasionally the same effect is produced as when a calculus is passing through the gall-ducts, viz. violent spasmodic pain at the epigastrium, frequent vomiting, with an unaccelerated pulse, and sometimes jaundice alternating with intervals of good health. Although the resemblance is great, still, when the two paroxysms are carefully compared, some points of distinction are to be made out. In the case of gall-stones, the irritability of stomach and vomiting I have found to be almost invariable attendants; there has generally been jaundice to a greater or less degree, with white stools and bilious urine. Several, if not all, of these symptoms may doubtless attend some cases of hydatid tumors, but they are not essential, and may be absent. In the case I have recorded none of them were present. In the case of calculus, the stools suddenly assume a bilious aspect after the cessation of the paroxysm, not so in the hydatid paroxysm. The situation of the pain in the above case was different from that in calculus; the pain in the case above related commenced a little to the right of the umbilicus, coursed up the back to the shoulders and the head, reaching the teeth, and rushing down into the arms. The character of the pain may not be the same in other cases; still, it is proper to note the points of disagreement between the account of the paroxysm given by Dr. Kerr, and what was observed in this case, especially as it may assist materially in enabling the practitioner to distinguish between hydatid tumor and gall-stone, disorders which a non-professional person would not wish to be confounded by his medical attendant. In the case recorded there existed another point of difference; the pulse was accelerated, being as high as 120 per minute. The pain seemed to me to be fully more severe than what I have remarked in cases of biliary calculus, and decidedly less remitting.

It has been mentioned in the report

that the fluctuation was most distinct at the region of the liver; it might be inferred from this that the fluid whose movement was felt was the fluid in the liver itself. This was not the case, no fluctuation was felt in the liver; but the movement of fluid between the abdominal walls and the anterior surface of the liver was well ascertained, and much more distinct than I had ever before felt it, in no inconsiderable experience. The fluctuation being more distinct at that part than at any other of the abdomen, arose from the absolute resistance which the extended and very hard liver offered to the retreat of the fluid under the hand. The liver felt as resistant as a board. It is important to attend to this fact, as it may assist in the diagnosis in future cases, and the more especially since it is placed as a diagnostic sign, in the article on Hydatids, in the Cyclopædia of Practical Medicine, that the tumor, "if it should consist of hydatids, will generally feel to a certain degree soft." The opinion that the liver was hard was verified by inspection after death, for it felt as tight and hard as a drum; and so distended was the tumor that even out of the body the fluctuation was not particularly well-marked.

The extreme tenuity of the parietes of the cyst is a striking feature in this case. In several parts of the tumor the thickness of the containing sac was not greater than that of a lady's kid glove. Such was the only partition between the immense mass of hydatids and the abdominal cavity. Hence there was considerable risk of rupture into that cavity, and the sudden occurrence of alarming symptoms. The danger from this source was not diminished by the presence of abnormal adhesions between the liver and the adjacent parts, such as are often found in cases of abscess of that organ. There is much reason to believe that had the patient survived many weeks longer, effusion would have taken place into the abdomen, and caused excruciating agony. It is interesting to observe that so long back as the time of Hippocrates, this accident and its danger were not unknown. He says, 'Οχοσοισίν ἂν τὸ ἥπαρ ὕδατος πληθὲν εἰς τὸ ἐπιπλοὺν βαγῇ, τοιτεοσιν ἡ χοιλίη ὕδατος ἐμπιμπλαται· καὶ ἀποθνήσκουσιν.—*ΛΗΗΟΝ*.

The diagnosis of this disease is comparatively seldom made out, except when the hydatid formation is dis-

charged from the body, and then the diagnosis is at it were effected for us. The importance of great attention to the diagnostic characters of the disease, on the part of students and young practitioners, cannot be denied. The utter impossibility of detecting the hydatid tumor, as such, without careful examination, and comparing its characters and the patient's symptoms, history, and condition, with the characters of the various diseases with which it may be confounded, must be acknowledged. Were proof wanting on this head, it would be sufficient to refer to the paucity of cases in which where there had been no discharge of hydatids during life; the nature of the disease had been pronounced before examination after death. There is no doubt difficulty in the way of a correct diagnosis, yet that difficulty may be overcome, and its presence, far from daunting the medical practitioner, should fire his energy, knowing as he must that the more he effects the more he merits, and the more he will ultimately attain. "*Tu ne cede malis; sed contra audentior ito.*" When the disease has been of long duration, when it is connected with an obvious cachectic condition of body, when the surface of the tumor is smooth, and especially where obscure fluctuation is perceived in the part, hydatids may be suspected. Scirrhus of the liver may be suspected when there is a decided cancerous character in the family, when the tumor is of moderate size, uneven on its surface, and when the symptoms of constitutional disturbance are of an acute character; the diagnosis will also be materially assisted by the presence of cancer in any other part of the body.

The presence of medullary sarcoma may be inferred when the tumor is of rapid growth, when it is soft, when there is much constitutional disturbance, and when encephaloid disease is, or has been, observed in any other part of the body.

Hydatid tumor of the liver may be distinguished from the enlarged liver depending on congestion, and arising from disease of the heart by the peculiar characters of the tumor already given. The congested liver is connected with disease of the heart; the liver is simply enlarged, and is not accompanied for the most part with severe symptoms,

such as we meet with in hydatid tumor.

Many remedies have been confidently recommended for the cure of hydatid tumor in the lower animals. The removal of cattle from wet to dry pasturage, it has been asserted, has cured the distemper. The same thing has been said of change of diet, as from succulent food to dry grain and fodder. These means, we believe, however judicious and useful, have not cured the distemper, but only arrested its further rapid extension. It is true that Jenner maintained that the disease could be produced at pleasure in the rabbit by feeding him on succulent food, and it might be concluded that the disease could be cured by an opposite kind of diet, on the principle that with the cessation of a cause the effect will cease. But we are disposed to question the correctness of Dr. Jenner's statement; the feeding of rabbits on succulent diet does not generally lead to the formation of hydatids. Moreover, if it did, it is extremely doubtful that the cessation of the cause would remove the disease. It might certainly arrest its further progress, but it could not remove a hydatid tumor already formed, any more than a good diet will remove a tubercular formation in the lungs caused by deficient nourishment.

Much, too, has been said of the utility of common salt, turpentine, broom tops and digitalis, when exhibited to sheep affected with hydatids, but it requires no profound knowledge of the nature of the disease to suspect that the chief results of their exhibition have been palliative only, and not curative.

Dr. Kerr suggests, that in the treatment of the disease in man we would do well to take a hint from the treatment pursued among the lower animals. I certainly agree with him, if he intends to confine his recommendation of these remedies to that moderate extent in which they may be safely employed as palliatives or arrestants. To administer violent and poisonous agents, however, with the view of destroying hydatids in the human body, or of causing their absorption, I regard as very questionable treatment. To tear up, as it were, the very vitals of the system, and fritter away the resources of the constitution in a vain and necessarily fruitless effort, is worthy of all condemnation.

While it appears that no medicinal or dietetic plan of treatment offers any reasonable probability of curing the hydatid, it is no less certain that nature, taking as it were upon herself the duty of the surgeon, has, by means of those powerful and effective actions, those primary levers in the surgeon's hand, viz. adhesive or plastic inflammation and ulcerative absorption, effected the complete eradication of the disease. How often have hydatid tumors which had long oppressed and fretted the suffering patient, and which threatened ere long to put a period to his sufferings by death, been cured by the hand of nature—how often have immense hydatid collections been discharged by the lungs, by the stomach, by the bowels, by the urethra, and by the surface of the body, and the released patient permitted again to enjoy the pleasures and discharge the duties of this life? Many such cases are on record—cases cured by the hand of nature, while medicine, impotent, has but looked on. But we cannot in all cases depend upon a natural expulsion; in many doubtless there is no effort made, and in many the progress is so slow that the patient expires before its completion. Again, the expulsion may take place into the abdomen. Doubtless many go down to the grave under such circumstances. Would it not be well to imitate the course so successfully adopted by nature on many occasions, at that season when the life of the patient becomes endangered, and produce an artificial outlet? It is true, that such procedure has been already adopted, and with success. So long ago as the year 1691, Dr. Tysons published an account of a girl whose side he caused to be opened a little below the short ribs, “whence issued out abundance of limpid water; but what was most surprising, together with it a great many hydatids, that first and last we guessed there might come out about five hundred of these bladders.” When he wrote, “the patient was still living, and enjoying her health better than all her lifetime before.” In this case it is uncertain whether the hydatids were in the liver or in the peritoneal cavity.

When the tumor can be distinctly felt, when fluctuation is discovered, and there are present the other symptoms

and circumstances indicative of hydatids, might not an artificial outlet be formed through the walls of the abdomen? There are, of course, objections to this course, amongst which may be placed, the uncertainty of the diagnosis and the danger of peritonitis. It has been already shown that with minute attention to the case the diagnosis may be made out with tolerable certainty, and it is probable, with future experience, less difficulty will be experienced. But in order to be assured of the nature of the disease, the tumors might be explored by a hollow needle capable of removing a specimen of the morbid formation. In the case of hydatids we would obtain serous fluid, which perhaps on minute examination may be found to possess characters diagnostic of it from common serous fluid: in the case of abscess we would obtain pus, and in that of cancer, cancerous cells, visible under the microscope.

ANALYSES AND NOTICES OF BOOKS.

“L'auteur se tue à allonger ce que le lecteur se tue à abréger.”—D'ALEMBERT.

The Retrospect of Practical Medicine and Surgery; being a Half-yearly Journal, containing a retrospective view of every discovery and practical improvement in the Medical Sciences. Edited by W. BRAITHWAITE, Surgeon to the Leeds Eye Infirmary, &c. &c. Vol. IX.—January to June, 1844.

THERE can be no doubt of the usefulness of such books as this, the title of which has just been read. When we turn over its leaves, however, short way as the time lies behind us which it purports to survey, a feeling of melancholy takes possession of our mind; we seem as if we were treading among the graves of the dead; evidences of previous life and motion meet us everywhere, but alas! in many cases the life has fled, the motion has come to an everlasting stand-still.—We do not mean to say by this that there has been anything like a particular murrain among our friends and acquaintances, and that it is the narrow heap covering their dead bodies that we encounter; it is but the tomb of their ideas, their

discoveries, their noble efforts to take the edge off the fell scythe, and the point off the deadly dart, that we meet as we wander through Mr. Braithwaite's *Retrospect*. Some two centuries ago, Theophile Bonnet, or Bonetus as he was called, a physician of note in his day, published an enormous folio volume, under the somewhat startling title of *Sepulcretum*, or the Burying-place. Morgagni followed essentially in the same track as Bonetus, in his celebrated work, although it came forth with the happier designation of a treatise on "The Seats and Causes of Disease." These great men may therefore be said to have provided tombs for the patients they attended: practitioners in the present day, and what are called practical men in England especially, show little or no disposition to find mausoleums for those that trust them; to hear our medici, it would seem that each had discovered the elixir of life in the particular case or class of cases he describes, and that his patients all became possessed of immortality through his means. The patients do not die then; but the reputation of the means which in the hands of the original proposers were sufficient to save almost all without exception, seem to come to speedy end.—One might write a *Sepulcretum* of therapeutical means in the present day. Nevertheless, discouraging as is the backward view of methods and means of cure which always meets us, we would not, we dare not, be ignorant of our want of success; and a large measure of this negative information we always obtain by turning to such books as the *Retrospect of Practical Medicine and Surgery*.

Mr. Braithwaite's is, so far as we know, the only attempt that has yet been successfully, and for a series of years, made in this country, in surveying the brief past with reference to matters of practical medicine. Our German neighbours have long been in possession of more than one work of this kind in their "*Jahrbücher*," and "*Repertoriums*." We remember, indeed, with regret, that it was not regularly continued, the excellent retrospect of medicine and surgery which used to preface the volume of the old *Medical and Physical Journal*, in the days when the apathetic medical public were content to have their latest information the 1st

of every month. We ought also to mention with respect the excellent reports that have lately from time to time appeared upon particular subjects both of scientific and practical medicine in the pages of our cotemporary, the *British and Foreign Medical Review*. But Mr. Braithwaite's is the only disjunct and separate retrospective medical review that has ever gone beyond a single number or volume: he has reached the 9th volume of his laborious undertaking—laborious we may well call it, aware as we especially are of the vast amount of application and pains which each of his volumes represents.—We trust that it will continue to appear for many years to come.

The work is really what it purports to be, particularly with reference to the literature of British medical periodicals; but as in one or other of these almost every work of any importance, whether British or foreign, is sure to be mentioned, and as Mr. Braithwaite does not by any means confine himself to selections from original communications, but also culls from critical and analytical notices of books, his work virtually becomes a kind of digest of the practical medical literature of Europe. We have but one fault to find with Mr. Braithwaite, and it is for the way in which he presents us with the results of his labours. It seems to us that something more than mere arrangement under the comprehensive heads of "Medicine," "Surgery," and "Midwifery," could be almost as easily accomplished, as the jumble, without method or sequence, which meets us from beginning to end of each of the sections. The first article, for instance, under the head of Practical Medicine, in the 9th volume, is on the Diagnosis of Empyema; the 2d is entitled Remarks on Urinary Disease. Under the head of Surgery, the first article comprises a review of some of the most important subjects treated of in the late lectures of Sir B. Brodie. Here, perhaps, arrangement was not very possible, nor yet very necessary; but a miscellaneous article need not have been followed by "Remarks on the treatment of Vesicovaginal fistula," nor that by one on the treatment of Entropium and Trichiasis."

The first article in the Midwifery department is "On the Effects of Ergot of Rye on the Fœtus in Utero;" the second on "Puerperal Fever;" the

third "On the Extirpation of Diseased Ovaria." It would be every whit as easy for Mr. Braithwaite to arrange his materials in something like a sequence; to place the diseases in the order of Cullen's Nosology, at the least, or according to the system or systems of the body which they implicated; or, perhaps as good as any thing, to place them alphabetically. We beg to suggest a natural arrangement to Mr. Braithwaite, for his next volume. He might arrange diseases that were referrible to no particular system, but which implicated all, such as fever in its various forms, to one head; then he might have a head to include diseases produced by specific poisons, such as syphilis, glanders, hydrophobia, &c. In another grand division he might have diseases which affect the ultimate structure of the various organs of the body, and which tend to engender new tissues, such as Cancer, Tubercle, Melanosis, &c. He might then connect each of the special diseases with the particular system of which the organ affected forms a part: what so natural, for instance, as to arrange all the diseases of the chylopoëtic organs into one harmonious group, *ab ore ad anum*? beginning with the lips, teeth, tongue, and fauces, and passing on to the stomach and intestines, liver, spleen, pancreas, &c. How easy would it be to bring all the diseases which affect the thoracic viscera into two harmonious groups, connecting with the one all the diseases that have their seat in the air-passages and lungs; with the other, all those that implicate the heart and pericardium, the arteries, the veins, the lymphatics, and the lymphatic glands, and with this, farther, to connect morbid alterations of the circulating fluid. The diseases of the brain and nervous system, again, form a most natural family; so do the diseases of the kidneys and of the skin, which are now viewed as the especial depurating organs. Finally, the diseases of the male generative system form one natural family, and the diseases of the female generative system form another. The trifling objection which we have raised to Mr. Braithwaite, is, however, and after all, one merely of form: each volume is provided with an excellent index, so that every article it contains can be referred to without difficulty; and in the 9th volume, now before us,

we are happy to find a general index to the contents of the first eight volumes of the work. With such ample means of finding out every thing the work contains, arrangement becomes of secondary consequence, though we still think it desirable. Were it even less to be desired for the reader's sake than it is, we venture to suggest it to the laborious author himself as a means of deriving a greater amount of satisfaction from his work than he has yet obtained. It is nothing that the statuary moulds a beautiful head, a fine bust, and graceful limbs, apart from one another; he must put them together into one harmonious and proportionate whole, and then, and only then, does he feel the thrill of exultation and delight that flows from forethought and design successfully shown forth in fact. The dissipated and the gay talk of their pleasures,—they are nothing to the joys which the true student feels in his quiet chamber. We know Mr. Braithwaite must be a happy man, because he must needs be an industrious man; we offer him a means of additional gratification in the coordination and arrangement of the materials which his knowledge and judgment lead him to select as worthy of a place in his pages. We very heartily recommend our readers to possess themselves of his unpretending volumes.

MEDICAL GAZETTE.

Friday, October 4, 1814.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

OUR NEW VOLUME.

THE LONDON MEDICAL GAZETTE has now appeared regularly for the period of seventeen years. Always in the hands of gentlemen who have not only been members of the medical profession, but practitioners themselves, it has been the unvarying advocate of all that is respectable in the profession of medicine and surgery, the science and practice of which it has ever sought to advance, by bringing

light, never by casting shadows ; it has sought rather to raise all to the level of those who by the accident of fortune, or position, or superior talents had achieved the highest places in the profession, than to pull these men down to the lowest levels. If mistakes have ever been commented on in its pages, it has only been that a beacon might be fixed on some sunken rock or shoal, not that those who had made shipwreck there might be gibbeted and exposed to scorn, and the confidence of the public shaken in all through the error of the one.

Uncertain of the character and convenience of any new structure that might be raised, the *MEDICAL GAZETTE* has still advocated the propriety of maintaining the old professional tabernacles in their integrity ; of mending and enlarging them, not of demolishing anything and building up anew. The profession has proclaimed all over the country that it approves the prophetic misgivings of the *MEDICAL GAZETTE*.

In one word, the *MEDICAL GAZETTE* will proceed in its course of unfettered criticism, both on the letters and the politics of the medical profession, meddling as little with the latter as circumstances will permit : what appears in the shape of quackery and false pretence it will denounce ; what comes forth in the guise of true science it will cherish and uphold. Old friends promise their unabated support, and the volume just commenced it is confidently anticipated will not fall short of any of its predecessors in scientific interest or practical utility. Whilst we shall meantime keep clear of any long and systematic course of lectures, we still propose to give several shorter incidental courses, and occasional essays in the form of lectures, by which variety will be secured and much valuable information given. The medico-political storm in which we have lately been engaged

must by and by blow over, and we shall then be left at liberty to revert in our weekly articles to the subjects that are of permanent and peculiar interest in our profession—the ethical, the educational, the practical.

THE COMMENCING MEDICAL SESSION.

THE admirable Discourse which heads this number leaves us little to say in the way of counsel and caution to those who are now entering on their career as students of medicine,—a serious business, and full of importance, as understood by older heads ; only lightly thought of by the ignorant, the giddy, and the young. Our friend Dr. Lee has presented the student with the glass in which he ought to look at himself, not only every day, but every hour of the day. No higher pattern can be proposed for imitation than Dr. William Hunter ; the influence of accomplishment, the fruit of untiring application, was never more brilliantly illustrated than in his complete success, and the signal influence he was enabled thereby to exert on the progress of the art and science of healing. Without his attainments as a liberal scholar, Dr. Hunter would not have been chosen to fill the place of tutor in Dr. Douglass' family, and without this appointment he would not have remained in London, not only signally to advance the most useful of all the sciences to mankind, by his own efforts and contributions, but to mould the clay, and to breathe the breath of life into the statue which he fashioned, and finally presented to the world as John Hunter, the glory of British surgery, the greatest comparative anatomist and profoundest physiologist the world has seen since the days of Aristotle.—Without the liberal elementary education, unquestionably wrang in great measure from adverse circumstances by his own indomitable

will, Dr. William Hunter could not have taken the subordinate office which finally inducted him into the distinguished position of leading physician in the metropolis of the world; he must have returned to his village, and there probably would he have lived his day—unnoticed and unknown.

We have said that the study of medicine was a "serious business," and so in sooth it is; but it is also a delightful one: the whole realm of nature is its subject, and the accomplished physician and surgeon are in the end but the interpreters and ministers of her laws—they create or originate nothing; the business of their early lives is to learn these laws, that of their riper years to apply them. The period of two or three years usually devoted to the study of medicine, the tyro ought to be aware is but as so many months or days in comparison with the extent of science necessary to constitute the accomplished practitioner. Let the student make the most of his brief time, then, and neglect no opportunity of informing himself on the subject of his profession. With diligence he can easily master all, and much more than all, that is required of him to pass his examinations, and to obtain his license to practise.

The habit of application is just as easily formed as that of idleness and dissipation; the true student grudges any interruption to his studies even as sincerely as the idle and dissipated man does any interruption to his idleness and dissipation. The pleasure that flows from mental occupation is at least as great as that which flows from frivolous amusement or sensual indulgence; and it has the infinite advantage, that it not only leaves no sting behind it, but that it brings both profit and reward. "Who," exclaims the poet, "of all the noisy train that fluttered round me once, clung to me to the last? Thou, friendship, with the

gentle hand, and *occupation*, thou." "The best present which God has made to man," says a French philosopher, "is the necessity of being occupied." We beseech our young friends to keep this great truth ever present to their minds: let them go on steadily day after day, week after week, without haste, but without a pause, and the month and the year will surely find them better and wiser men than they were before. In the end they will be able to present themselves upon the list of candidates for reception into the medical profession, without misgivings of success, and without the pangs of self-reproach for neglecting opportunities, and time misspent, which the idle and the dissipated never fail to suffer. They will be able to offer themselves with manly confidence for examination upon the strength of what they have themselves learned by diligent application through the whole term of their studentship, not with mistrust and a sense of humiliation, confiding in what they have crammed in the course of a few weeks or months through the degrading process of grinding.

MOVEMENT IN THE PROFESSION.

Writing the few lines that precede has carried our mind back to our own happy student's days, and wakened notes whose very sweetness unfits them to combine in the rough and often discordant combinations that make up medical politics. We begin, in fact, to be weary of the sameness of the song that is everywhere sung: our friends all over the country have but two, or it may be three, fundamental resolutions, which they still enforce in nearly the same words,—the necessity of protection to the profession against quackery, approbation of the Court of Examiners of Apothecaries' Company, and perchance thanks to the Editors of

the *Times* and medical journals for their advocacy of their cause. The demonstration against the Medical Bill, in its present shape, has been quite unequivocal; what the profession would have in its stead is much more questionable: we have numerous letters and suggestions on the subject, which we have not the courage at this moment to consider and comment upon, but which we shall, of course, revert to by and by. Meantime, and by way of winding up our notes of the movement in the profession, unless we come upon anything that is striking or new, we shall print a petition to the House of Commons, that was agreed on at a highly respectable meeting of medical practitioners,—physicians, surgeons, and apothecaries—held at Rochester on the 27th ultimo. This petition sheweth,

“That although your Petitioners regard with satisfaction some of the clauses contained in the proposed Medical Bill of Sir James Graham, yet on the whole they view it with disappointment,—disappointment and alarm; for while it professes to protect the medical profession and the public health, they believe it to be directly and seriously injurious to both.

“That your Petitioners are of opinion that the Act passed in 1815, and called the Apothecaries’ Act, has tended much to elevate the character and protect the interests of the General Medical Practitioner, and to secure sufficient medical attendance to all classes of society. That the abrogation of this act, in the present state of the law regarding the medical profession, would, they believe, prove a serious injury to the members of that profession and to the community at large, the real interests of both being inseparably connected; and thus they think ample security should be afforded against all unqualified practitioners, and feel great regret that the proposed Bill contains no clause to such effect.

“They therefore humbly and respectfully pray of your Honourable House to give to the proposed Bill your most serious and mature consideration, and not to pass it into a law in its present form.

“And your Petitioners will ever pray.”

MEDICAL REFORM BILL.

To the Editor of the Medical Gazette.

SIR,

CONJOINING with many of my professional brethren in testifying my thankful sense of your able and judicious analysis, and tendency of the proposed bill of Sir James Graham on Medical Reform, I beg to trouble you, and, if you think fit, your readers, with a few observations on this, at present, engrossing subject. No doubt you are amply supplied with several gratuitous communications relating to the Bill in question, and have recommended to you as many modes of supplanting or amending its several clauses—showing that what is remarked of men and opinions in general, much more might it be said of our order, *tot medici, tot sententiae*. The observations, however, of one who has gone through the several grades of the profession, both in public and civil practice, may not, perhaps, be unacceptable, and be considered somewhat in the light of experimental acquaintance with the workings and wants of the profession, especially in the provinces.

The Bill of Sir James Graham contains three principal enactments, upon which, it may be said, all the rest of the other clauses depend for their operation and detail. These are—1st, the creation of a Board of Health to consist of 18 members; 2d, the abolition of the present Apothecaries’ Act; and 3d, the registration of all regular practitioners.

We must give the Home Secretary due and worthy credit for his desire to establish this Central Board for to control, systematize, and equalize, the *curricula* of medical education throughout the sixteen or eighteen *dejecta membra* of our universities, colleges, and corporations, now all acting as independent sources of education and honours, and conferring titles and privileges of unequal repute, jarring with each other, and, from time to time, giving rise to much ill-will, invidiousness, and legal injury, among the general members of the profession.

The formation of such a Board seems therefore to be the main pillar in any reconstruction of the profession; and it was natural that the architect, who may also call himself the proprietor, should form this pillar after his own *order*, and irrespective of the taste or wishes of those who were to enter within the precincts of the structure when completed.

In your late leading articles you have stated some powerful objections to the structure of this part of Apollo’s new temple; or, in plain words, how the liberal show of eighteen members of the Board, representative, medical, and lay official, will be divested of any

practical power or control, and be soon absorbed into a plenary quorum at the Home Office. There is nothing to prevent this, if designed; but if not, convenience, love of peace, and respect to governmental authority, will bring it about.

Instead, then, of a Board liable to such tendencies and objections, and to found its basis upon some show of representation, it should rather be composed of a medical representative from each of the Universities, Colleges, and Medical Corporations in Great Britain and Ireland, that are empowered to grant degrees, diplomas, and licenses to practise medicine and surgery; the rules and bye-laws of this Board to have always the approval of the Lord Chancellor for the time being before they can be issued or put into execution.

The principal office of this Board should be to establish a uniform course or curriculum of study throughout all the seminaries of medical and surgical education in the three kingdoms; and all degrees, diplomas, and licenses emanating from which to have corresponding privileges to practise equally in any city, town, or other parts of Her Majesty's dominions, without let, fee, or hindrance.

The second principal object of the Bill is the abolition of the present Act of the Company of Apothecaries, without the substitution of any enactment of similar legal import of protection to the regular, and of restriction on the irregular practitioner. As this is really proposing a most important change in the polity of the profession, no wonder it has excited much alarm, and stirred up universal reprobation throughout all its ranks and degrees. Viewing, however, this subject in a practical bearing, it is quite a question whether the profession will suffer more from this *free-trade* system than they do at present from a protection that is merely nominal or inoperative, and altogether deceptive. I need not bring forward any proofs of this—he that runs may read them in the hosts of irregulars, quacks, and doctoring druggists, that abound with barefaced impunity in every town and village of the empire. It may have the show of some protection to the licentiate of the Worshipful Company to know that the sword of Damocles hangs over the head of all those practising outside the pale, but assuredly the “pharmacopolæ, mendici, mima, balatrone, et hoc genus omne,” have no such terrors. They know that this sword of the law hangs not by a hair, but by a multitude of cords; while its suspension in any wise proves often an injurious and an insulting check to the otherwise more amply and more honourably qualified member of the profession. Not satisfied with the present delusive protection,

I am sorry to see that the over-weening desire of many members of the profession to enforce their privileges, is making them cry out for summary penalties against all and sundry intruders and regular practisers of medicine. This clamour for restriction will never gain any support or sympathy from the public; on the contrary, it will place us in a more invidious position, for every sacrifice is expected from the profession—time, money, charity, physical comfort, and relinquishment of all public or political status. To assert any thing like protective rights, or enforce any fiscal penalties, would not be endured. We must yield. To carry into force any prohibitory enactment of this kind would be to close up the great bulk of the chemists' and druggists' shops throughout the kingdom. These ready retailers of advice and medicine are the physicians and surgeons of the lower classes; they can fee no higher grade; they are, from poverty and convenience, compelled to go to these minor oracles without the gate; for the pulling a bell, or lifting a knocker at a consecrated door, implies a deeper pull at the bottom of their purses than they can afford.

We must, then, either permit chemists and druggists to play with disease and death over their counters, or a lower or subordinate class of practitioners must be licensed, similar to the former humble apothecary, or the pharmacien of France. It may be a *lese majesté* against science and the profession, to say, that the present growing race of professional men are too highly educated; but so it is, as far as the great masses of the poor and working classes are practically concerned. They will have a doctor suited to their own wants, feelings, and ability to pay him. In fact, the rising profession has, in education, habits, and, we may say, in honourable ambition, outstripped the under sluggish, if not retrograde current, of lower society. Their adaptation to each other is becoming every day less reciprocal, and it is only through the halls and waiting-rooms of hospitals and dispensaries that they mostly come in contact; but there it is with humiliation on one side, and with a sense of sacrifice of time, or of condescending benevolence, on the other; while there is little of “*ab eo curari, a quo volunt.*” It may therefore be concluded that it is very immaterial whether the penal part of the Apothecaries' Act be retained or not; while it would be inconsistent and intolerable to public sentiment to enact any prohibitory laws of a penal nature to put down irregular practice or quackery.

The third principal head of the proposed Bill—the registration of all regular practitioners—may be held a wise and useful measure, though it is delusive and onerous in

its intended administration. It gives a show of privilege and exclusive protection to the regular practitioner, but nothing more than he at present enjoys. The governors and trustees of all medical institutions throughout the kingdom do already elect no medical officers but such as are duly qualified. This wise and palpable rule requires no Act for its enforcement, which would be no boon nor protection to the regular practitioner, nor any bar or prohibition to the irregular one in what he wants—practice that *pays*, not that *honours*.

As to the evidence or certificates of registered practitioners being alone received in Courts of Law, this will easily meet with its value, when we know that the great majority of medical men in any respectable practice rather avoid than court these occasions of professional duty, and it would be rather a privilege to them to be debarred from these forensic exhibitions. This part of the Bill, even if it were an exclusive boon to them, will be very apt to be at times frittered from them; for cases may easily be conceived where the medical evidence of a long-practising irregular, of a sound and sober mind, cannot, for the ends of justice, be rejected.

As much may be said of the value to the registered practitioners, of being alone, in opposition to the unregistered, able to recover his account of charges at law. This is speaking with an uncertain sound; for at present physicians cannot recover in law their fees; yet do they suffer? And assuredly, for every account a surgeon or apothecary recovers in a Court, he may reckon to lose more than double its amount among those who either are or would be his patients; for medical men must endure all things without repining.

The proposed mode of registration is, however, directly onerous and sumptuary without any equivalent protection, while the law will protect the right of a patent medicine after receiving the duty for the privilege of selling it. And really, to raise a considerable sum of money from the regular profession, without any *quid pro quo* of effective privilege or protection whatever, is certainly much more than the wildest reformer among us ever dreamt of; and will make us adhere with unwilling tenacity to our ancient ways. Registration is, however, very desirable; but let it be simple, untaxed, and satisfactory. Our diplomas might be sent in to the Town Clerks of cities and boroughs, or to the Clerk of the County wherein the practitioner for the time resides, on the presentation of his degree, diploma, or license, and this at the expense of a fee not exceeding £5 in any case. These local registers would be revised by the Central Board or Council, and the revised list printed each year, the

original list being open to the inspection of all and sundry, at the respective offices of the said registrars, and only those whose names are therein registered to be entitled to claim any of the rights, honours, or privileges, of the profession.

Though much more might be remarked by me on the fertile subject of this Bill, so full of hard and indigestible bits, though larded over with some savoury morsels, yet as it seems designed by its author to undergo a long and repeated rumination, before any thing like a wholesome and comfortable digestion will take place, I may take another occasion of intruding upon you the better concocted observations of

AN OLD PRACTITIONER.

September 16th, 1844.

VISIT TO SALERNO.

No medical traveller visits Italy—or ought to visit Italy—without seeing Salerno, whose situation and climate seem to have given it medical supremacy in the beginning of the 12th century My guide to the University was one of its Professors, who seemed disposed to show me every attention. Though charged with the duties of one of the principal chairs of medicine, he did not live in Salerno. He only came at the hour when his three or four pupils required his presence, and discharged his function as quickly as possible; he strode his mule, and returned to his household gods in the country, where I imagine he gave no farther thought to physic, for his farm required the greater part of his time.

The university where theology, law, and physic, live peaceably together, rises midway upon the acclivity on which Salerno is built. The building has nothing of the antique or striking with which imagination loves to encompass the head-quarters of the world-renowned Scuola Salernitana. It is a small mean-looking house, the walls of dazzling whiteness, the windows closed with green-painted shutters. I scratched the wall with my nail, I looked eagerly for some symptom of antiquity in the foundations of the walls, but nothing of the kind was to be seen. The house had in all respects the air of the country box of a worthy citizen of Paris. I visited the chambers of medicine, of law, of theology, and saw a few students, save the echoes of whose footsteps and my own all was silent.

I next visited the cathedral; but this too had lost its ancient character; modern restorations had given it a bastard and uncertain physiognomy. The sole vestige of the once famous school of Salernum is no longer in the city: in a convent of Benedictines, dedicated to the Holy Trinity, are contained the historical relics of the former grandeur of

Salernum; they exist in the shape of an immense library, which boasts a collection of no fewer than 50,000 MSS. Surely there must be something precious, something interesting in this immense collection; but who can tell? The Benedictines of Salerno, forgetting the laborious industry of their predecessors, live in loathsome indolence, and reckon nothing either of letters or science. They show their MSS. with pride to the traveller; but the most important MS. of all in such circumstances, is wanting,—there is no catalogue!—*Ed. C. in Gazette Médicale de Paris de Sept. 21.*

HYPERTROPHY OF THE CARTILAGINOUS STRUCTURE OF THE TRACHEA AND BRONCHI.

By PROFESSOR GINTRAC.

BACCHI, native of Bourdeaux, eight years of age, of a feeble constitution, with the chest narrow, sternum prominent, and the breathing always more or less affected; often suffered from pains in the chest, on account of which he was several times admitted into the hospital, and relieved by general and local bleedings, and the application of blisters between the shoulders. On the 24th of May he was readmitted, labouring under great difficulty of breathing, amounting at times to suffocation. He had no cough, and the voice was neither raucous nor whispering. Auscultation only indicated marked bronchial wheezing; percussion was sonorous throughout; the heart's action regular. The patient was pale and thin. Various means were employed, such as assafoetida injections, fumigations with datura stramonium, ipecacuanha, in alternative doses, digitalis and scammony, sulphuret of iodine, but without producing any decided change in his symptoms. On the 8th of July he left the hospital, but came back at the end of a fortnight labouring under the most aggravated dyspnoea, and died on the 8th of August.

On examination of the body, the lungs were found adhering to the cavity of the chest, excepting at the summit of the left lung, where there was a little clear serum. The pleura was thickened, and separated with greater ease from the ribs and intercostal spaces than from the surface of the lungs. The larynx was healthy. The trachea was free in its upper two-thirds, but in its lower third it was closely united behind to the oesophagus, and in front to the large vessels by means of dense cellular tissue. The trachea, when separated, appeared larger than natural, but on opening it throughout the whole extent its parietes were found considerably thickened, especially at its lower part close to its bifurcation. The parietes of the canal were seven millimetres in thickness; they were dense, elastic, white, and of

a fibro-cartilaginous appearance. The calibre of the trachea, in consequence of the hypertrophy of its parietes, presented a remarkable diminution; it was reduced to five millimetres. The lungs were oedematous; the inferior lobe of the right lung was hepatized. The thymus gland was rather large. The heart, stomach, and intestines, were healthy. The liver was enlarged, and adherent to the diaphragm, kidneys, spleen, and arch of the colon. Its tissue firm, granular, and red.—*Gazette Médicale, September 7.*

LECTURES
ON THE
NATURE AND TREATMENT OF
DEFORMITIES,

*Delivered at the Bloomsbury Square
Institution.*

BY R. W. TAMPLIN, F.R.C.S.E.
Surgeon to the Institution.

Talipes varus non-congenitus—Talipes valgus—Talipes equino-varus—Talipes equino-valgus.

IN my last lecture I pointed out the character and treatment of talipes varus congenitus, and mentioned that various causes had been assigned for this deformity, but that, in my opinion, the position of the child in utero was the most probable, as no spasm nor evidence of disease is found in the nerves or brain; contraction of the muscles alone exists, the patient possessing voluntary power over the contracted muscles as well as over the muscles that are kept on the stretch, (elongation would imply increased length of muscle). I also stated, that I did not believe in structural shortening of the muscle, as, in the case I had an opportunity of examining after death, the divided ends of the tendon were brought quite into apposition, although no trace of the deformity remained, and the little patient had exercised the voluntary motions of the deformed foot with as much facility as those of the other foot, which had not been thus affected; that in infants you had to contend only with *muscular resistance*, but that in childhood, and in adult deformity, you would experience a greater or less amount of resistance from the contraction of the ligaments of the joint, which rigidity would require the most steady extension to overcome; that in the adult, and also in those who had walked for any length of time on the deformed foot, you would find a great obstacle

to the cure of the deformity from the increased arch of the tarsus and metatarsus, the fifth metatarsal bone being forced inwards towards the metatarsal bone of the great toe; that in all cases the division of the contracted muscles, *i. e.* the posterior and anterior tibial muscles and tendo-Achilles, was necessary, and very frequently the plantar fascia also, together with the long flexor of the great toe—at all events, in those cases in which any great degree of contraction existed there; that in infants these muscles should all be divided at the same time, but that in adult and younger patients who had used the deformed foot much, and where there was great rigidity in the ligaments, it would be necessary to divide the posterior tibial and anterior tibial muscles, and if necessary (which it very generally is) the plantar fascia also, and to abduct the foot before dividing the tendo-Achilles; that rest and warmth must be enjoined here, as well as in every other case; that extension was not to be commenced until after the punctures should be healed. I also described the method I have adopted in dividing the posterior tibial tendon, namely, by puncturing the fascia, and introducing a blunt-pointed knife between the bone and tendon, so that no risk could be incurred of puncturing the artery; that a complete division of the artery had been found to be of no moment; and that I had effectually (when this division had occurred) stopped the hæmorrhage by the application of pads of lint and bandages. I would also recommend you (in the event of dividing the artery, which event you will always be enabled to discover from the jet of blood following the knife, and from the sudden pallid condition of the foot) not to attempt extension for a week afterwards, as you might run some risk of disturbing the clot, and thus producing false aneurism. In the case I mentioned, in which this occurred, forcible extension was made by the hand four days after the operation, at which time

there was no evidence of false aneurism, and the puncture was completely healed; so that I have always suspected that the clot in this instance was disturbed. Should you meet with false aneurism, I would advise you not to postpone the attempt to secure the artery, but at once to lay open the sac, and take up the artery by means of the needle and ligature, as you cannot expect, save in adult cases, to secure the artery by taking it up alone. I also pointed out to you the necessity of artificial support. The support I find most successful is an upright support, (with a stop-joint at the ankle), reaching from immediately below the knee, and fixed in the sole of the boot, with the strap attached to the sole on the outside, the strap passing directly over the instep to buckle on the inner side, below the stop-joint at the ankle; so that constant pressure is kept up on the instep, at the same time that the flexion of the joint is allowed; and by these means the patient is enabled to take exercise immediately that the foot is restored to its normal position; thus attaining a double benefit, the exercise of the muscles in their proper position, and the advantage which the patient derives from air and exercise; the ligaments, or passive agents, also gaining strength during the time they are so exercised in their proper position. It is also as well never to allow the patient to sleep without a support of some kind, until the foot will maintain its position unassisted, and until the cicatrix has resolved itself into its permanent condition. I must again remind you, that the greatest perseverance is necessary, as well as care and attention, or your efforts will certainly be frustrated; and should you improve the foot without completing the cure, rely upon it a gradual relapse will follow, whatever care you may take to prevent it. I have had in my private practice cases that had been operated upon several times. In one case the tendo-Achilles had been divided three times, and the foot had been brought into a tolerable position; yet, by inattention to the details of the after-treatment, and by neglecting to complete the removal of all contraction and rigidity of the muscles, as well as want of attention to the motions of the joint, a relapse took place, and greater obstacles were placed in the way of treatment than existed in the first instance. In fact, so great is the additional resistance of the tendon after redivision, that the cure becomes very tedious and troublesome, requiring the most unremitting and constant extension,—far more than is necessary upon the first division of the tendons.

I shall now proceed to describe the species of deformity called talipes varus non-congenitus. In this deformity you have the same relative position of the bones, muscles,

and elongation of the ligaments, but rarely if ever the same amount of rigidity. It arises, 1st, from the irritation of teething, as, in fact, does almost every distortion of the foot; 2dly, from inflammation of the joint; 3dly, from measles, small-pox, and any cause of irritation of the brain and spinal marrow. When it arises from the irritation of teething, or any cerebral irritation, it comes on gradually, either preceded by complete paralysis of the entire side or extremity, or of the abductor muscles solely: frequently the deformity is combined with talipes valgus of the other extremity, of which we shall have to speak hereafter. Upon the recovery from complete paralysis, one or more muscles remain paralysed completely; and, of course, those recovering their lost power, having no active opposing force, draw the foot in this or that position, according to the muscles so affected.

In talipes varus non-congenitus the tendo-Achilles will be found contracted, and the posterior tibial muscle, occasionally the anterior tibial, will be found paralysed; and the deformity appears, in some instances, to have been determined by position, the weight of the body pressing the foot over, and thus producing it; and this would be more likely to produce an inversion than an eversion of the foot, when the heel is completely elevated. In all cases of non-con-

FIG. 1.

Illustration of talipes varus non-congenitus, taken from a boy fourteen years of age, both feet being affected from the irritation of teething when two years old.

genital deformity, where partial paralysis coexists, you have a greater amount of atrophy of the entire limb, especially below the knee, when it is confined to the foot, as in this instance; and you will find that definite outline, so conspicuous in congenital talipes varus, equally entirely absent; but there will

be an unnatural smoothness of the foot, so much so, that you will, after some experience, be enabled to tell at first sight a congenital from a non-congenital distortion. There is also, as I before mentioned in *talipes equinus*, a diminished nervous power, the limb rarely retaining its natural heat even during the summer months; and in the cold weather patients thus affected suffer periodically from chilblains.

Patients afflicted with non-congenital *varus* suffer much more pain and inconvenience in walking than those who are afflicted with congenital *varus* only, as the cushion, upon which they walk, is much more quickly and easily irritated, owing to the diminished vitality, or nervous power, of the skin, on the one hand, and from the relaxed condition of the ligaments on the other; for although the ligaments, from position, become contracted, yet they do not possess that tone and rigidity which they do in congenital deformity; and the ligaments on the external side of the joint, namely, the external lateral ligaments, which have become elongated, do not appear to hold the foot sufficiently firm to give steadiness to the joint; hence the great weakness experienced by the patient.

When the cause of deformity arises from inflammation of the joint, you have of course no paralysis, nor any effect similar to that just detailed, the deformity having been occasioned by position; and you will rarely find that complete inversion of the foot which is found in congenital cases, the patient walking more on the anterior and outer side of the fifth metatarsal bone, (vide fig. 1) and the foot having amore uniform sweep from the *os calcis* to the toes. I have a case of this kind now under treatment, in an hysterical female, where inflammation has been for some time existing in the ankle, and the foot has gradually become inverted by the constant action of the anterior and posterior tibial muscles, together with the *gastrocnemius*; no paralysis existing in the *peronei* muscles. But the anterior tibial, and also the posterior, as well as the *gastrocnemius* muscles, are in a constant rigid condition, without the foot being touched, or any force being applied to abduct it.

The treatment of non-congenital is precisely the same as the treatment of congenital deformity; that is, the division of the anterior tibial tendon (if contracted), the posterior, and the tendo-Achilles, as well as the plantar fascia. You must direct your attention especially to the natural heat, and proceed more cautiously with the mechanical treatment than you will find it necessary to do in the congenital deformity, from the inability of the skin to bear much continued pressure without its vitality being destroyed, which must be most carefully guarded against, as this interferes with and prolongs the treatment, allowing the newly-formed

substance to gain strength, without your being able to extend it when newly formed, and thus increasing the difficulty in the after-treatment. After the foot is brought into its normal position, greater care will be required to keep it so, as the attachments of the joint being weakened from the general loss of tone, and one or more muscles being paralysed, it appears, and is in fact, comparatively unattached, and will yield in any direction it may be pressed in by the weight of the body; so that you must see the necessity for the most perfect and firm support after the foot is in position; which support will, in all probability, be required for years. You cannot be too minute in your directions to the machinist, or in cautioning the patient. In this case, also, the foot must be supported during the night, as any motion, even without the weight of the body, keeps up the play allowed by the relaxed condition of the ligaments, and prevents their contracting upon themselves, which they will do even in these paralytic cases, if the position is constantly maintained, and the muscles have become sufficiently strong for the patient to walk with a common boot without support. But this must be the result of time.

In contractions arising from disease, of course you will not think of operating until all symptoms of disease have disappeared. You may, however, improve the position of the foot and prevent an increase of deformity by carefully applying a splint, and by the constant and almost insensible extension you can keep up by means of a bandage; which at the same time that it prevents and diminishes the deformity, also assists the restorative process by keeping the limb perfectly steady, so that the patients experience great comfort from it; and this method may at all times be adopted, and will not interfere with the treatment you are pursuing in order to remedy the disease under which the patient may be labouring.

After the disease has subsided, the tendons should be divided in the usual manner, and then proceed with the mechanical treatment; and as soon as the foot is brought into position, exercise the motion of the joint, to prevent it becoming fixed by the adhesion or alteration of structure in the synovial membrane; this can be done by means of the instrument, which will effect it with less pain to the patient, and with more certainty, than by means of the hand. As a guide in the treatment of *talipes varus* generally, the patient ought never to suffer a sufficient amount of pain to interfere with his general health or rest. The most severe cases may be treated in such a way that the patient will be subjected to very little or no pain if proper care and due diligence be used by the medical attendant; of course there will always be found more or less uneasiness

from the constant stretching of the ligaments of the joint. This applies not only to varus but to every deformity, and will be found the safest as well as the most speedy method of cure.

We now come, gentlemen, to another species of deformity of the foot, viz, talipes valgus, or flat foot, vulgarly called splay foot. This deformity is exactly the reverse of the last considered, and I would first draw your attention to the anatomical condition of the foot, as this deformity more than any other depends primarily for its cause on the ligaments or passive attachments of the sole of the foot. It will be recollected that the calcaneo-scapoid ligament, and the ligamentum scaphoideo cuboideum plantare, together with the ligaments connecting the scaphoid bone with the cuneiform bones, form the principal support to the arch of the foot, *i.e.* passively; you have also the plantar fascia with the flexors, which assist materially, as well as the muscles of the sole, and the tendons passing into and through it; but these muscles cannot and do not exercise much influence except during the active condition; they depend in a great measure on the integrity of the form of the foot for their perfect and full amount of motion. Now the arch of the foot must be considered as a double arch; first, the natural arch, as understood generally, extends from the heel to the great toe, and 2dly, the lateral arch, or bridge from side to side, formed by the scaphoid, cuboid, and cuneiform bones, and extended to the tarsal extremities of the metatarsal bones; and the points of pressure are the posterior inferior extremity of the os calcis, and the anterior inferior extremity of the metatarsal bone of the great toe, and the anterior inferior extremity of the fifth metatarsal bone, or little toe. Now as long as the bones of the foot are held in their natural position, and no paralysis of the moving powers exists, free motion and elasticity in walking is derived from the arches described; but the moment the arch of the foot is diminished, the motions of the foot become limited, and ultimately, in the more severe cases, where the arches are entirely destroyed, it is altogether lost. The origin, then, of this deformity is a weakness or congenital elongation of the ligaments of the sole, and the muscles having a weakened instead of a firm point of insertion (for their insertion must not be regarded individually but collectively) will, in their action, assist the weight of the body in increasing the malposition. This deformity is both congenital and non-congenital, as you may have anticipated, and consists in a yielding or falling of the arches of the foot, the os scaphoides projecting and touching the ground on its inner and under surface, the head of the astragalus separated, of course, slightly on its inner side from the corresponding articular surface of the os scaphoides; the ligaments

I have before mentioned connecting the scaphoid with the os calcis. The scaphoid, with the cuboid and cuneiform bones, become elongated, and allow the arch to sink. The internal lateral ligaments become secondarily affected and elongated, and allow the astragalus in some cases to fall, and thus to lie obliquely in the articular cavity, whilst the external sides of the os calcis is approximated to the external malleolus. This

FIG. 2.

Illustration of congenital talipes valgus, in which may be observed the most complete flattening of the foot, no trace of an arch being left.

is the foundation, and what I imagine to be the origin, of this species of deformity. The next change that takes place is the abduction of the anterior portion of the foot, *i.e.* from the head of the astragalus, and appears to arise in the following way:—as the firm connection of the bones of the foot is destroyed, or for a time lost, it would yield in any direction in which it might be drawn by the muscles passing to and through and over the tarsus during their natural action, and as the extensors of the toes. The peroneus tertius on the dorsum, the peroneus brevis on the outer side, and the long peroneus passing beneath, have a powerful leverage in consequence of their passing under the external malleolus; hence the long extensors of the toes and the peroneus tertius in their action have a secondary effect in raising the outer edge of the foot beyond its natural position in part only, not altogether. The peroneus brevis and longus have also a secondary effect, *i.e.* abducting the anterior portion of the foot; hence the contraction from position of these muscles, and, as will be seen afterwards, the necessity of their section. With regard to the congenital form of the deformity, I have told you in my last lecture

that it is position in utero, and position alone, which occasions this kind of deformity as well as other congenital deformities that exist without malformation. There is no evidence whatever of spasm existing; the muscles are contracted, but not spasmodically; for I understand by the term spasm an irregular action of the muscles which is produced during the exercise of volition, and in defiance of volition. Spasm is never found to exist in the deformities I have mentioned, nor in the particular one now under consideration. In the congenital there is a more complete flattening of the entire foot (vide fig. 2); it is not confined, as in some instances of non-congenital deformity, to the internal side of the foot, but extends, as in the case before you, to the entire foot; there being no trace of an arch left, or in all probability none had ever existed, but from the circumstances before pointed out the muscles before mentioned had become contracted. The same diminished development of the muscles is here evident as in congenital varus, but to a much less extent, as although there is certainly a contraction of muscles mentioned, yet from the nature of the deformity the contraction is much less, and admits only of a limited amount of contraction compared to the great change in the position of the foot in talipes varus, and although contracted they possess great powers of motion—excepting only in the most severe distortion; and even here, as must be obvious, the extent of contraction cannot be very great. The non-congenital T. valgus arises generally from the patient having been in the habit of carrying heavy weights, or from being for many hours successively on his feet—at least these are the causes usually assigned. But there can be little doubt that there must be a predisposing cause, viz. general debility, which renders those suffering under this distortion incapable of bearing that great quantity of exercise or bodily fatigue which persons whose existence depends on their daily labour are compelled to undergo. We have had two remarkable instances of this deformity lately in the institution. The one a boy about 17 years old, the other about 20; the former was a gravedigger, the latter a farmer's labourer. The first thing which attracts the attention of the patient to this deformity in its incipient state, is a sense of weakness, more especially on the outer side of the ankle-joint, and the projection of the scaphoid bone with the head of the astragalus: they then observe the flat appearance of the sole of the foot, and the tendency of the inner ankle to approach the ground in walking: as the deformity increases, the pain in the joint and the sense of weakness increase to such an extent that the patient becomes totally unable to follow his ordinary occupation. And although the

FIG. 3.

Illustration of the most severe form of non-congenital talipes valgus, taken from a patient *æt.* 17, both feet being similarly affected.

FIG. 4.

The above, after treatment, which occupied three months. The anterior tibial, extensor communis digitorum, peroneus tertius, longus and brevis muscles, were divided.

internal malleolus does not touch the ground, yet it appears to do so. In the majority of cases the contraction becomes permanent of the peronei and extensor of the toes, which will be found prominent, and extremely tense on any attempt to adduct the foot, offering the most dense and unyielding resistance, and in the case of the gravedigger above mentioned, the anterior tibial tendon also became contracted; I imagine, from the constant instinctive efforts made to raise the arch of the foot. In such cases the joint becomes immovable, which arises, I suppose, from the circumstance of the astragalus lying obliquely in the articulation—its inner edge fallen, and its outer edge raised. Thus the synovial membrane becomes pressed upon constantly on the two lateral points of pressure, which it is not accustomed to bear. This, with the constant stretching of the ligaments, is the cause of the pain, which at times is most severe.

In some cases of non-congenital talipes

valgus you will find the whole ligaments of the foot in a loose state, allowing of undue motion in any direction; it is not confined to those supporting the arch, but it is extended to the whole foot: here you will find no contraction of the muscles. Although when the foot is pressed upon by the weight of the body it is perfectly flat, yet when raised from the ground the patient possesses power to move it in any and every direction, so that time is not allowed for contraction of the muscles to take place. For instance, when the foot is on the ground, the peronei and common extensor muscles are somewhat shortened, or have a diminished extent of motion; the moment the foot is removed from the ground the anterior and posterior tibial muscles raise the arch, and then each alternately being elongated or shortened, no fixed position is maintained. The peronei muscles are not permanently shortened, and consequently no contraction arises. We have amongst the out-patients at this time a case in point. It is a difficult variety, because there is no fixed point to act upon, and the great difficulty which will be found to present itself is the maintaining of the foot in a constant position, for if this position cannot be maintained a cure cannot be effected. And the difficulty of maintaining this position is much greater than you would have anticipated *à priori*; it being not a part, but the whole of the connection of the bones of the foot that requires support. In true talipes valgus congenitus I have never found paralysis of the muscle, but in a species of valgus which I shall hereafter mention, it is a common occurrence. I have met with the deformity, where it was supposed to arise from rheumatism, in the case of a patient about 40 years of age, at least that was the cause assigned, and when I first saw the patient he was suffering from some rheumatic affection. The peronei muscles were exceedingly tense as well as the extensors of the great toes. The arch was fallen, but I have reason to believe that the circumstance of the rheumatic affection first drew his attention to the deformity, as I ascertained upon inquiry that he had experienced a weakness of the joints for some time previously. Strange as it may appear, patients suffer much more pain and inconvenience from this species of deformity than from the more severe distortion of varus.

CARUS'S EARTH-LIFE — A SPECIMEN OF IDEAL PHYSIOLOGY.

To the Editor of the Medical Gazette.

SIR,

I HAVE derived much pleasure from observing that you have of late occa-

sionally published translations and abstracts of the best foreign essays in the higher branches of physiology, and have encouraged your friends to communicate them by your own example, and by giving up to them a certain portion of the most important section of your journal. Your custom cannot fail to exercise a good influence on the profession. We are all too apt to degenerate into mere routiniers—to let our intellects be unoccupied till they are fit for nothing better than the routine of the trade of our profession. We need, at least once a week, to be roused by seeing how actively others are pursuing science, and to be tempted to exert ourselves to attain their knowledge, or detect their errors, or, at the least, to keep up the habit of thinking upon somewhat more than we learned years ago.

Having profited, I hope I shall be allowed, in return, to contribute in the carrying out of your design. In this view I inclose an abstract of the chief part of a work by Dr. Carus, long known as one of the most accomplished of modern physiologists, and lately better known (and highly esteemed for his social as well as his scientific qualities by all who had the pleasure of forming his acquaintance) as the attendant physician of the King of Saxony. He is a practitioner, and, I believe, a very good one. The contemplations in which he indulges occupy a different portion of his mind from that which is engaged in the daily business of his profession, and science and practice do not interfere with each other.

The work* appears to me one of the best examples of the ideal physiology by which so large a section of the scientific world of Germany is captivated. I am not sure that the system is substantial; yet it is strange, and much in its favour, that something of the kind has been in the thoughts of some of the most enlightened philosophers of nearly every age. But, whether it be true or not, the mind may be well exercised in considering it; it has all the beauty of poetry, and more of religious feeling than our own utilitarian systems of physiology have; and if it have not the truth of science, let the reader prove its errors, and catch somewhat of the spirit of reverential

* "Zwölf Briefe ueber das Erdleben, von Dr. C. G. Carus." Stuttgart, 1841.

contemplation in which it seems to have been written.

I will add, only, that I have taken pains to make the translation as literal as possible; the obscurity of which some may accuse my language is strictly copied from the original; and I am not sure that much of what is peculiar to this system would not disappear if it were expressed in ordinary language. But my design has been to give an example of ideal physiology as it is. — I am, sir, yours and your readers' servant,

L.

Sept. 12, 1844.

THE grand error, says Carus, into which men commonly fall in their contemplations of the universe is, that they imagine, as it were, two natures; one living, the other not living; in one of which they include the nature of men, animals, and plants; in the other that of the earth and heaven, and their phenomena. But "whoever, unfettered by prejudice, attentively observes the life of all nature, finds everywhere one and the same essence and operation in the life of the celestial bodies, and in that of the terrestrial beings more nearly related to ourselves. In the ever-whirling sphere of the planet, with its in- and ex-halations, the regulated circulation of its waters, its magnetic and electrical vital exercises, he discerns nothing essentially different from what he sees in the infusorium rolling round with oscillations in the water, and in the circulation of the fluids in the higher creatures, the results of magnetic and electrical oppositions." Nor are the elements composing the bodies of the one class different from those that make up the others. "Do not the same hydrogen, carbon, oxygen, and nitrogen, the same metals and metalloids, that are dispersed throughout terrestrial nature, make up the individual organisms; nay, even man's own body? Are they not the same elementary actions, such as attraction and repulsion, electrical and chemical energy, which work alike between the strata of the earth and of the atmosphere, in the growth of plants and in the motions of animals? In a word, is not nature ONE SEA of being, in which an infinite diversity of ideas are in a thousand ways reflected, and whose drops appear in myriad forms, as at every instant they arrange

themselves according to the law of this or that idea? The same carbon lived yesterday, perhaps, in our blood, which to-day floats still active in the atmosphere, and to-morrow may work within the germinating plant. In truth, then, there can in no case be any question about a difference of organic and inorganic, of living and dead, elements." Things differ, not in their real and inherent nature, but according to the idea or design which for the time is embodied in them as members of one universe.

To form a definite conception of nature and organic life, it is indispensable to have a clear notion of the meaning of the words "organic," and "organism," and of the relation in which nature stands to them. Now, "if we derive them from their origin in *"οργανον,"* what else can an organism be than an instrument or member, generating, producing, and so exercising its life, according to the guidance of the idea, whether conscious or unconscious, that dwells within it? Every such organism or member, in so far as it is a being appertaining to nature, is a manifestation of her ever-changing elements, and so is *manifold*; but in so far as its existence is determined by a prime-design, *by an image of its being previous to its being*, it belongs to the ideal world, and so is an unity, an individual. In the former view it has what we call a body; in the latter what we name the soul, whether conscious or unconscious. Inasmuch, then, as the complete manifestation of the organism depends on its proper idea continually and intimately pervading its changing elements, we say,—the idea, the soul, incorporates itself in it, enlivens it, and it becomes *living*.* Life, then, can properly mean nothing else than the permanent incorporation of the prime-design in the being, or of idea, in nature." And if we now proceed to a wider and freer glance over the world, our inmost consciousness will at once say that this notion of the incorporation of the "living essence" is as well adapted to the whole universe as to each single organism; and that, therefore, "of necessity life must rule through all the spheres, and that the real and absolute opposite of life, a

* It is not possible to express the full force of this passage in a translation. The German *Leben*, life, being derived from *Leib*, body, *einleben* may mean either to incorporate or to enliven.

genuine and complete death, is utterly impossible, and to be classed only with the notion of an absolute zero, or a complete negation."

All nature, then, is animated, and "may be compared to an infinite sphere, whose centre is everywhere, the periphery nowhere. Nor is this a mere poetic image; its truth may be proved with mathematical accuracy. For what is the distinctive character and proper notion of the sphere, but that it is a form in which all the possible diameters are exactly equal? And if the infinity of nature must be admitted as self-evident, will not all the conceivable diameters that can be drawn through any given point in it be equal, *i. e.* equally infinite? And again, while the spherical form is proved by the equality of the diameters, must it not also follow from the infinity of the sphere, which excludes the notion of a bounded periphery, that every possible point in it may be taken as a centre through which the infinite and all-equal diameters may be drawn?"

From these considerations there plainly follow some important consequences in regard to the primary form of all organisms. It must be remembered that "the entire macrocosm, that is, all nature, animated and pervaded by the divine ideas, the great Immeasurable, as one comprehensive living whole, is to be considered as the source and aggregate of every particular form and manifestation of life; and from this again it plainly follows, that every single being, every individual, every particular organism, can be regarded only as a part, and indeed as one integral part, of this immeasurable whole. It is further self-evident, that every integral part of a whole must partake of certain essential properties of that whole. Wherefore, if, as before stated, the principle of the spherical form be really and of necessity proper to the universe of nature, then may it be at once explained why every single organism must present, or rather must embody, the spherical as its primary form."

To this first law of formation must be added a second, namely, "that the formation of an organic whole cannot take place except from the fluid state. For how can the formation of that which is defined, bounded, and shaped, come to pass except from that which is

undefined, and as yet unbounded, and not fixedly shaped? But if the fluid be just that form of substance which has no determined boundary, and yet, in respect of boundary, is infinitely determinable, we see at once the necessary foundation of this second great law of nature"

And again, a third great and general law of nature, which is indeed hardly more than a corollary to the first, is that each individual organism must exhibit more simplicity both in its form, and in the intrinsic and extrinsic exercise of its energies, the further we go back into the history of its former life; so that in every respect an organism always proceeds from greater simplicity to higher complexity.

Now nothing can present a more striking example, and at the same time a more decided proof of the truth of these positions, than the history of the formation of the heavenly bodies, as it is represented to us in that of those "cosmical infusoria," the meteoric stones. Of these "Chladni has rendered it most probable that in the infinite space of the universe spherical masses of vapour form, and float about." These may be believed to be vapours of such metals as by combustion form earths, and to be produced by a diversification of the ether that fills all space; and "when they come in contact with the earth's atmosphere, they are set on fire by an electrical discharge, and either pass away, giving a moment's light, and then disappearing in the form of shooting stars, or else, by more thorough burning, melt into drops of various size, and then, attracted by a planetary mass, fall down upon it as meteoric stones. And if we now consider that that heavenly system which comprehends our own earth, and which is best known to us, shows us certain *fixed* forms which exhibit on a large scale the two in which these cosmical infusoria are manifested, namely, 1stly, nebular and indeterminate bounded spheres, and 2dly, others denser, and bearing evident signs of original fusion—of which one set are called comets, the other planets—these observations acquire a far higher import; they promise to us many nearer conclusions even on the formative history of the planet we inhabit, and they may serve besides as striking and illustrative examples of the three stages

of formation just mentioned" For we have in them the primary spherical form, the fluid material, and the formation of divers solid crystalline substances out of it.

But the simple phenomena of a drop of water will illustrate the same laws; and the understanding that has once apprehended them, or rather the mind that has once perceived them, for they are objects of the reasoning faculty, will be able to comprehend at once a number more. The drop of water, then, presents to us the purest liquid in the simplest form of individuality; and, is it not marvellous! if I isolate a quantity never so small of this fluid, and let it float in space, at once there is aroused within the mass of as yet undetermined, though infinitely determinable, shape, the all-pervading vital principle: the idea of unity works in it by the attraction of its whole mass to one centre, and as this attraction is of necessity the same through the whole of the uniform mass, that form is at once produced whose radii are all equal, that is, the sphere; and the mass of water, now a drop, has made the first step in organization, but unless further excited, remains fixed and restrained in this stage; for the idea which has enlivened it is not powerful enough to maintain its manifestation with any constancy against the restless tug of the elements Yet still there hovers over this drop of water as a prototype of its being, or as an ideal model, a law, in which is decreed a solid form to be assumed under certain conditions,—and we call this production of a solid form, before invisible, but by an inherent law decreed, out of a fluid, *crystallization*; and we recognize it as one of the most remarkable processes, as a process, an act, by which originally everything which appears to us in a fixed solid form, whether it be called stone or plant, earthy or animal body, was determined. Rightly to comprehend this simple formative process is indeed to comprehend all formative life; for through all the grades of complexity of formation, we have nothing but this act, which in the crystal is shown in its first power (for in it the form once attained is permanent), carried on to the 2d, 3d, or it may be the *n*th power, as at the end of some cycle the being (a plant or an animal for example, in

each year or any other period,) changes its form.

But to return to the drop of water: so long as the electrical tension between the different parts of the planetary system, which we call heat, pervades this fluid sphere in a certain high degree, it does not succeed in satisfying its tendency to individual formation; but if this tension sinks to a certain degree, then that bond of universal life is loosened, and individual life attains strength to exhibit itself: then it is that that which just now floated in the space, a clear and fluid sphere, now rendered crystalline by cold, on a sudden floats onward as a solid six-rayed star; till a renewed permeation of its substance by an electrical radiation of heat again, through a retrograde metamorphosis, produces the simple spherical form, and converts the solid star again into the round fluid drop.

All this is but an image of the plan that prevails through the entire universe; there is in it neither empty space nor rest; and though our senses cannot tell us what fills the heavenly space, yet our reason and analogy assure us that it is that original formative element of all the bodies of the universe, that element of all elements, which merely is, but is utterly indifferent, and therefore not in any wise sensible, and for which the best name is ether (from *ἀέθέρ*). Now, if we suppose that, as in our own minds, the awakening idea proves itself in the most varied images and operations, so the Divine Idea established in ether endless differences and vital tensions; then the outward radiating eccentric tension will appear to us as Light, the concentric constraining tensions as Gravity; and a formation of heavenly bodies giving light and gravitating towards one another will be intelligible. And if we remember that every organic being must first appear in spherical form, and first move in a sphere, we attain to the simplest conception of the cosmogeny or formation of the universe. But further, just as in the development of the egg we see the arrangement of structure around structure, of encircling or peripheral around central or middle structures, so in the mightiest cosmical phenomena the same foundation-law rules; and hence the necessity of certain spheres becoming central, while other peripheral spheres,

coincidentally developing themselves out of the ether, form a system of worlds something like our solar system.

A glance at our own solar system shows us plainly the different developmental stages of these structures, in the series from the meteoric nebular comets to the single planets; thence to the sun-like planets that have moons; and lastly to the sun himself: for here we see a production of the definite out of the indefinite in form, and a progress from the peripheral to the central. But all this is far more striking when we look to that series in development in which we have first those unbounded nebulous spots in the firmament covering spaces inconceivably great, yet visible only with the most powerful telescopes, and apparently fixed, like the stars themselves, far beyond the nearest of which they lie; then, those yet smaller grouped and rounded nebulae in which the brighter spots give a real light, and that more intense at the centre than around: and lastly, the two brighter nebulae that are visible even with the naked eye in Andromeda and in the sword of Orion.

Proceeding from these examples to the consideration of the necessarily analogous formative history of our earth, we may first point out the arrangement of the elementary substances, which are all products from the ether, in a series according to their several grades of development; from those nearest to the ether, the hydrogen, oxygen, &c. to those which are most nearly perfected in their fixity, and have attained the nearest to that state to which all tend, namely, the noblest metals, gold, silver, &c. Light, heat, and electricity, it must also be remembered, are not bodies, any more than seeing, hearing, and feeling, are organic tissues, but "the original vital and sensual energies of the ether moved by the divine idea and differing itself. The ether sees and illuminates, it feels and warms, it polarises and is electrical;" and from it, light, heat, and electricity, are derived to all bodies as energies in which the life of all matter manifests itself.

The first appearance of our earth, then, may be conceived to have been in the form of a nebular sphere of ether condensed into gas and vapour, rotating on itself and around the sun, and diversifying itself. From this enormous

mass of condensed and polarizing ether, we may venture to imagine how, in the time which we call the origin of the earth, the several elementary substances issued forth; how enormous masses of the vapours of silicium, kalium, &c. were borne out of it, and formed a denser rotating vaporous sphere: how the primary gases, oxygen, hydrogen, and nitrogen, came forth, and how the discharge of electrical polarity between the Empedoclean elements of earth and air produced the two other elements of fire and water, the former in the burning of the metallic vapours into liquid, molten earths, the latter in the form of watery vapour, as the product of the combustion of the hydrogen and oxygen. And with this, the first period of creation ending would pass into the second, which would be distinguished by the state of the cloud-enclosed fiery liquid; and on this day we may conceive that the earth was one huge drop of glowing molten earths, surrounded by an atmosphere of gases and of watery vapour. The most terrific volcanos, the loudest storms, the fiercest earthquakes, all combined, would be but an air, a breath, in comparison with the fearful strife of raging forms in such an elemental planet. Yet must formation still go on; and in the third day we may believe the solid form produced. From the analogy of the development of the egg by the formation of solid peripheral layers around the central fluid mass, and from some appearances about the earth itself, it is probable (though the crystallization of the drop of water indicates otherwise), that this solidification commenced on the surface of the liquid sphere, and proceeded to a thickness of about 170 miles towards its centre. In the interior of the hollow sphere the molten fluid state is still preserved, as it probably is also in parts of the earth's walls; a condition again comparable with that of the egg, for as in that we see currents of fluid blood remaining in the substance of the germinal membrane as it develops itself, and its surface becomes denser, so in the walls of long-extinguished volcanos there are constantly volcanic heats and development of gases. With the gradual cooling and solidification of metals oxydized by combustion so as to form quartz and lime, alumina, &c. was formed that shell of the earth which, as it con-

stitutes the deepest basis of all known kinds of rocks, is named primitive granite; but, coincidently with this, we may suppose was the precipitation of the cooled watery vapour of the atmosphere into the depressions on the shell, so as to form a primitive sea; and with this separation of water and earth would close the third period of creation.

But the tendency which there is in parts to follow the type of the whole which they compose, would engender the formation of numerous hollow spheres by gases and vapours heaving up parts of the earth's surface as it cooled; and these huge bubbles, when they opened and collapsed, would leave enormous basins, in which the first collections of the waters of the primitive sea would settle. And then, as all these actions still went on, new precipitates would fall from the ethereal nebula of the planet's atmosphere; masses of metallic earths would be dissolved in the sea, and, by the myriads of the lowest forms of animal life about this time produced, there would be engendered enormous quantities of lime (for lime is always formed in incubation); and thus with fresh storms and liftings up, and burstings of the granite, there would be great depositions of lime, which, burnt by the volcanic heat, would form the primary limestones, while from fresh meltings of the granite there might result, after the manner of lavas, the later forms of granite and of quartz. Now, too, as the watery vapours and the atmosphere gradually cleared, the light of the sun and of the wide firmament would break in upon the planet, enlivening and animating its surface; an epoch which may be regarded as the conclusion of the fourth period of earth's development, or of a fourth day of creation.

Just as in the seed or the egg the shell bursts when the young one has attained its full development, and as then first the new-born creature opens its organs to the light, and enters into free and self-dependent intercourse with the universe, so did the young earth appear through the bursting envelope of nebula, and now for the first time did the sun's rays, and the light from thousands of the heavenly bodies, act immediately upon the new-born planet. The result was the excitement of a new individual life; and from air, earth, and

water, as the concipients, and the solar fiery influx as the generant, myriads of new and higher individuals began to be developed, and a marvellous world of organic forms came forth; and then there was a fifth period, in which rest prevailed over the former storms.

It is difficult, indeed, to imagine how the larger plants and animals could be formed from elements, but it must be remembered that the first beginning of each of these is but a microscopic infusorial vesicle, and that therefore for these, as for all other beings, the only difficulty is the conceiving of the elementary generation of this vesicle. We may observe, too, that the stage in which each organism exhibits its power of generating new ones, is just that which immediately follows the attainment of its own complete development; and is it probable that the life of the earth is an exception to this rule, resting as it does on the very foundation-laws of organic life? When the elements first settled from their strife, must there not have ensued, under the exciting influence of the animating, polar, and even polarity-generating force of the sun, a higher and more significant generation of living beings than are produced from them in their later age?

It is most probable that the earth passed through its earlier stages of development far more rapidly than through the later; and just as in the organic beings which we can inspect, we find that the metamorphoses passed through are greater the nearer they are to the original production, so it seems to have been with the earth, in which the earlier changes were not only more rapid, but more striking than the later. After the production of animal life, and during what may be called the sixth period of the creation of the earth, it is probable that the changes it underwent were produced partly by its inhabitants, and partly by the atmosphere and the water precipitated upon it. If, in the present day, we see a constant mutual play between the air and the earth, a constant precipitation upon its surface of water from the higher regions of the atmosphere, and a constant absorption of watery vapours by the mountains; if we see a fine dust depositing itself upon the highest rocks from what appears to be the purest air, and me-

ON THE

PATHOLOGY AND TREATMENT OF
OVARIAN DISEASES ;

WITH CASES.

By DR. SAMUEL J. JEAFFRESON,
Physician to the Chelsea, Brompton, and Belgrave
Dispensary, &c.

[Continued from p. 865 of last vol.]

teoric stones falling, all increasing the volume of the earth; and if, in the belief that the earth is a hollow sphere, we may reasonably consider that the productive ether within it is also constantly adding to its substance; we can at once perceive that in the earlier periods of the life of our planet a more considerable deposition of these metallic vapours would be going on, and sometimes by gradual addition, sometimes by mighty revolutions, would constantly augment its mass. When a world of plants and animals had for a long time animated the earth's surface, and, by the addition of their calcareous and carbonaceous deposits, had increased its size, new eruptions and heavings up of the surface, new changes of the earthy products, would ensue. At this period, also, it is likely millions of marine creatures would die by the development of new metallic substances in the floods, and, sinking to their bottom, might be again raised up in rocks. Sometimes, also, the waters, forced from their beds, would stream over the land, burying together forests and animals; and all these things, perhaps, went on through a series of years, through the most varied cycles of storm and rest, till at last a fresh clearing up of the atmosphere—by this time probably again obscured by the old comet-like nebula—took place; again the enlivening light of the sun, and of the firmament, fell on the tranquil earth, and at the beginning of a seventh formative period of its life new generations of plants and animals came forth. At the length appeared the *MICROCOSM*, *MAN*, placed by a higher, finer, and more central organization, at the head of all terrestrial organisms; *Man*, whose consciousness was destined to reflect a ray of divine light, just as the sun's image is thrown back from the crystal clearness of the pure drop. And as the eldest tradition of the earth's creation ascribes six days to work, and gives the seventh for rest, so science indicates that the period extending from the last-mentioned to our own day has been one of constant comparative tranquillity.

THE *surgical treatment* applicable to the permanent cure of ovarian disease remains now to be considered. Nothing can be further from my wish than to go out of my own province and trespass upon that of the surgical members of my profession, who must necessarily be more competent than myself to draw just conclusions on the subject. I shall simply content myself with such a brief sketch of the prospects held out by surgical treatment as may enable the physician to estimate in some degree all the chances which may be afforded to his patient by means of art. With this view, also, I have, to the best of my ability, constructed a statistical table of the results of operations for extirpation of the ovaries: if this table should be found by surgeons incomplete for all the purposes to which it might have been rendered applicable, my only apology can be that it was never intended to do more than to afford a rough estimate of the value of this operation. It is next to impossible that physicians, or other practitioners who do not handle the knife, should remain perfectly neutral; it is simply my wish, therefore, to afford them some data on which, combined with tact and practical experience, they may afford opinions justly entitled to the weight which may be attached to them by the patient.

Two surgical means have been proposed for the cure of ovarian disease; the one consists in the introduction of foreign bodies within the cyst to produce a cure by means of inflammation, suppuration, &c., the other in the entire removal of the tumor.

The former intention has been effected by means of various injections in the instance of the more fluid tumors, thrown in after the removal of their contents, much as in the treatment of hydrocele. In the less fluid tumors, the same purpose has been effected by

more freely laying open the tumor, by leaving the trochar in the wound, or by introducing a bougie, strip of lint, or some other foreign body.

The results of this practice seem to have been of four kinds: death—no improvement in the condition of the case—temporary retardation of the progress of the disease—and permanent cure. So far as I can learn from a reference to published cases, the mortality of this operation does not appear to be so great as might reasonably have been expected; whilst in a fair proportion of cases it has effected permanent cure. Its employment has, however, almost invariably been followed by serious constitutional symptoms, and even in the most successful cases it presents the great inconvenience of a painful and tedious process, the contents of the tumor gradually running off for months or years by means of an open fistulous sore: during all this period, too, the patient, as well as the medical attendant, are kept in a painful state of suspense as to what may really be the ultimate termination of the case. Without in any degree anticipating the question of the propriety of the extirpation of ovarian tumors, yet the comparative rapidity of the cure, and the speedy comfort thus derived from the entire removal of so cumbrous a growth, may well entitle this mode of proceeding to a decided preference over the other; that is, in the comparison of successful cases of either kind: nor, indeed, would these advantages be dearly bought at the expense of some little increase of temporary pain, and slightly greater risk to life, the latter of which conditions, however, there appears no reason to believe is in reality the case.

If such comparison be just, the operation of extraction should therefore banish the former proceeding from practice.

The removal of ovarian tumors by incision through the abdominal parietes, an operation occasionally resorted to some thirty years ago, has only within the last few years been advocated by any considerable number of practitioners. If not the originators of the operation, British surgeons at least deserve the merit of having placed it upon any thing like a sure foundation.

Great difference of opinion still ex-

ists with regard to the propriety of this operation; and if the question were at once to be settled on the mere authority of opinion, the decision would probably be in the negative,—a large, perhaps the greater, proportion of those whose authority stands deservedly high in public estimation, being opposed to it. Such decision, however, neither can be or ought to be final; like other questions of a like nature it must eventually be decided upon its own merits: and it is more than probable that here, as in most other instances, truth will be found to lie midway between the opposing parties, and that whilst the one has to retract its decided veto, the other also may find the applicability of the operation less general than their at present sanguine expectations had induced them to expect.

The responsibility of either party is indeed momentous; for whilst it would be highly culpable, on the one side, rashly to vaunt a comparatively useless operation, fraught with imminent risk to life, it can be regarded as no less culpable, on the other, to lend its authority to the utter condemnation of a measure which may tend to the prolongation of life, and the diminution of human misery.

Abdominal surgery has of late years made great advances, and the practicability of operations must now rest, not upon suppositions of *what may be the case*, but upon facts, *what is the case*. It is in vain in the present day to say, “how can the abdominal parietes be laid open to the extent of from nine to fifteen inches, the delicate viscera therein exposed to the air, and the patient live?” This matter is decided; there are the facts before us. Believe them we must, in spite of their discordance with our preconceived notions. This, however, is but one step gained. Before arriving at any approximation even at a just conclusion, the risks and advantages of the operation must be carefully balanced against the risks and disadvantages of the disease. The probable results of the operation must be weighed against the probable results of the disease, left to nature, or combated by other means. The general as well as the especial obstacles to the performance and success of the operation must be carefully considered, as also its proportionate applicability to particular forms or cases.

I shall now take the liberty of drawing the reader's attention to the following statistical table* of the results of 74 operations for the extraction of ovarian tumors. The materials from which this table has been drawn up have been chiefly derived from the *Lancet*, *Medical Gazette*, and *Medical Times*; they have been also compared with Dr. Churchill's table in the *Dublin Medical Journal*, from which source three or four cases previously omitted by myself have been copied; and for an account of the three operations by Mr. Lane I am indebted to that gentleman himself, whose readiness to afford me every assistance and information, and desire to promote a strict scrutiny into the result of these operations, did equal credit to the kindness of his heart and the soundness of his judgment.

The table has been divided into three great classes.

1st. Of the cases in which the ovarian tumor has been removed by the large abdominal incision, the hand being introduced within the peritoneal cavity for the purpose of separating adhesions, passing ligatures on the pedicle, &c.

2dly. Of the cases in which a small incision has been made, through which the cyst has been drawn (first emptied of its contents, and tied externally); and,

3dly. Of the cases in which the removal of the tumor has been attempted, but abandoned on account of adhesions, or in which the tumor has been found to be other than ovarian, or in which no tumor has been found at all.

[To be continued.]

CASE OF EXCISION OF NEARLY ONE-HALF OF THE LOWER JAW-BONE.

By S. CHISHOLM, M.D. Inverness.
(For the *Medical Gazette*.)

THE operation in this case was undertaken under rather unfavourable circumstances, the patient being a man 68 years of age, and having been operated upon for carcinoma of the lower lip about six years previously. He was admitted to the Inverness Infirmary on the 22d of June last, for a tumor of the

left side of the lower jaw, which he stated first made its appearance about a year and a half ago, and has been gradually increasing in size. The tumor at the period of his admission was about the size of an orange, of a semi-fluid consistence, having a portion of the skin of an unhealthy hue, from the diseased connection of the morbid growth with the superficial parts. The face was very much deformed, and the mouth so distorted, that it was with considerable difficulty he could manage to take his food. His general health was tolerably good, although there seemed a tendency to chest complaint. At a consultation held on the case, it was unanimously recommended that excision of the diseased part should be performed, as the only means holding out the prospect of relief, at the same time that the disadvantages for the operator were fully admitted. The nature and extent of the operation having been explained to the man, and he himself rather urging its adoption, the operation was accordingly performed in the following manner.

After puncturing the tumor, and evacuating about an ounce of glairy fluid mixed with pus, an incision was first made from the condyloid process, down the posterior border of the ramus of the jaw, and along the margin of the bone to the chin, the diseased portion of the skin being included in an elliptical incision. An incision was then carried directly downwards from the angle of the mouth, to join the other. The flaps being sufficiently dissected from the tumor, and the jaw near the symphysis separated from its connections, so as to allow the finger to be passed round it, a groove about one-third the diameter of the bone was made with a small saw, and then, by means of the cutting forceps, the jaw was completely divided. The cheek was now further dissected from the tumor and bone, along the ramus of the jaw to the glenoid cavity; and after depressing the bone, the temporal muscle was separated from its connection with the coronoid process. This step of the operation was attended with some difficulty, owing to the powerful contraction of the temporal muscle; but with the aid of a sharp-pointed bistoury, passed up under the zygomatic arch, and around the coronoid process, the difficulty was overcome,

* The length of the Table prevents our giving it in the present number, but it shall appear in our next. — *Ed. Gaz.*

and disarticulation was then easily effected. The bone thus detached was turned downwards and backwards on the neck; and by proceeding with the dissection carefully, and close along the inner surface of the bone, the operation was completed with very little loss of blood. The internal maxillary and other arteries of magnitude escaped injury. The inferior maxillary branch of the internal maxillary, the facial, and two other smaller vessels, were secured by ligature, and the parts brought together,—the divided lip by the twisted suture, as for hare-lip, and the other parts by stitches. A pledget of lint soaked in cold water was applied externally, and the part bandaged up. There was no plug introduced in room of the jaw.

At the first dressing the parts looked well, and subsequently there was very little purulent discharge. The whole united by the first intention where there was a sufficiency of skin; but from the unavoidable necessity of excising the diseased portion of skin, an opening of considerable size remained to be filled up with granulations. The lip part united by the first intention, and the pins were removed on the fourth and fifth days. The granulating process in the open space was promoted with the nitric acid, and sulphate of zinc lotions, and continued to go on favourably; but one or two of the cervical glands, situated below the sore, became enlarged, and the granulations assumed a rather unhealthy aspect.

The man was now (end of July) removed from the hospital, in order to have the benefit of salubrious air and greater liberty to walk about. He finally left town for home on the 28th of August, having his health and strength so far restored, as to be able to undertake the journey of upwards of sixty miles into the highlands. At this period there remained a fistulous opening in the situation of the angle of the jaw, but it was gradually contracting under the use of the sulphate of zinc lotion; and at his own urgent request, his daughter having unexpectedly come for him, he was permitted to go home, with a supply of the lotion. The deformity was considerably less than prior to the operation, and he managed to take spoon meat with facility. At the period of his departure two of the cervical glands were considerably en-

larged, so that the man's immunity from further disease is very uncertain; yet temporary relief has been afforded by the operation, and with him it would have been highly satisfactory but for the constitutional malady, which threatens a new outbreak of malignant disease. I may remark, that notwithstanding the unfortunate season of the year (July), and other adverse circumstances, the discharge after the operation was not nearly so offensive as might have been expected in such a case; and this, perhaps, was mainly owing to the absence of a plug in the place of the jaw. I must say, that I do not see the necessity or advantage of a plug in those cases, although recommended on such high authority as it is. In this case it was totally inadmissible, from the extent of skin necessarily cut out entirely.

On examining the diseased bone after the operation, it was found to be affected with *spina ventosa*, originating in the cancellated texture of the bone, which had expanded into the size to which it attained.

Inverness, Sept. 13, 1844.

REMARKS ON
MR. PATERSON'S CASE OF UTERINE
HÆMORRHAGE.

To the Editor of the Medical Gazette.

SIR,

IN No. 51 (date September 20) of your valuable journal, the report of a case of "Accidental Uterine Hæmorrhage" is given, by Mr. Paterson, of Glasgow.

As I venture to differ from that gentleman, on the propriety of following in all similar cases the same plan of treatment he adopted, and as the subject is one of the utmost importance to the accoucheur, you will perhaps favour me by giving insertion to the following remarks.

The main features in Mr. Paterson's report are these. The patient was seized with severe flooding in the ninth month of pregnancy, which continued with but little interruption until delivery was accomplished. At an early period (*i. e.* on the first vaginal examination), the os uteri admitted the fingers, and was "*found soft*." The vagina was plugged, and the effect of the tampon very judiciously aided by external pressure.

An hour and twenty minutes elapsed, during which time four two-drachm doses of *secale cornutum* were given. Meanwhile an alarming amount of blood had been lost, and the prostration of the patient was correspondingly great. The os uteri was now found more dilated, and the membranes, which presented, protruding, they were *with some difficulty* ruptured. The hæmorrhage, however, "*threatened to continue*," and the administration of the ergot was resumed, as before. After the second dose labour pains set in, three of which sufficed to expel the fœtus, the placenta, and "*a basinful of coagula*." The patient, though reduced to a state of the most extreme exhaustion, survived.

The treatment relied on by Mr. Paterson for the safety of his patient in this instance, treatment which the result may seem to justify, and which, therefore, he advocates in cases even of "*unavoidable*" as well as "*accidental hæmorrhage*," however alarming, consists in the application of the tampon, with the addition of abdominal compression; in the exhibition of the ergot of rye in large doses at short intervals; and in the rupture of the membranes at as early a period as possible. The operation of "*turning*," he would altogether forego. Each of these remedial means will afford me opportunity for a few observations.

Opinions are very much divided as to the efficacy of the tampon in controlling hæmorrhage. For my own part, while I admit it to be a valuable adjunct to our other resources, I cannot believe with Mr. Paterson, that we can "*arrest hæmorrhage*" by its use, however firmly and uniformly the abdomen be at the same time compressed. If the separation of the placenta be extensive, and the flooding consequently severe, an oozing of blood from the open mouths of the utero-placental vessels must take place, its flow being only diminished, not suppressed, by the formation of coagula consequent upon the presence of the plug in the vagina. That it continued "*internally*" in Mr. Paterson's case is evidenced by the "*basinful*" of clots which immediately followed the placenta. Unless, indeed, the vagina be *thoroughly filled* by the tampon, it is worse than useless, for then it but masks the flooding which it cannot check.

Without attempting to enter upon the "*vexata questio*" of the virtues of the *secale cornutum* in producing uterine contraction, with a simultaneous dilatation of the os uteri, it is sufficient, I think, to refer to the details of the foregoing case to prove that it cannot be relied on. Twelve drachms of the drug were given in infusion in the space of about three hours, before expulsive action was established, and then not until the liquor amnii had been evacuated more than an hour.

To the most strenuous advocate of this medicine it must appear questionable whether the uterus acted in obedience to the stimulus of the ergot, or whether it followed the natural law, the impulse to contraction being given by the rupture of the membranes. Are we, then, to sit calmly down, placing implicit faith in the powers of the tampon to subdue the hæmorrhage, *however alarming*, and await hour after hour, the tardy, and always doubtful, effects of the *secale cornutum*?

On the expediency of rupturing the membranes at the earliest possible moment, in cases of "*accidental hæmorrhage*," there cannot be two opinions. It is no new fact that this measure is often alone sufficient to arrest serious flooding; but it is certain also, that the more complete the disunion of the placenta from the uterus, the less can we reckon on its beneficial agency, because the less probability can there be that the mouths of the bleeding vessels will be closed by the contraction of the uterus on its diminished contents. All the circumstances of Mr. Paterson's case went to shew that the separation of the placenta was by no means partial, if, indeed, it were not entire; the consequence was, the operation failed of success, the flooding continued, and the position of the patient became momentarily more and more critical. The rupture of the membranes must then be looked on as an expedient by which, in very many instances, all danger may be averted, but as a step *preparatory* only to the operation of "*turning*," should the hæmorrhage continue.

A few words on the subject of "*version*" will enable me to bring these remarks to a conclusion. For the old axiom touching "*meddlesome midwifery*" I have the highest respect, but "*mischievous*" as it is, that practice, I conceive, is much more culpable which

pertinaciously adheres to doubtful remedies, when a patient's life is hanging on a thread, and sets aside the only certain means of rescue, speedy delivery by turning. If after the rupture of the membranes the contractions of the uterus are not so prompt and so effective as to quiet all apprehension, version is as imperatively called for as in cases of placenta prævia. If, as Mr. Pater-son assumes, it be not a rule universally admitted to "turn" in placental presentations, it is at least so general as to need no justification from me, for it would be almost equally judicious to trust entirely to nature, because the placenta has occasionally been thrown off first, and the patient survived, as to expect that in an arm presentation the position would be naturally rectified, or spontaneous evolution take place.

Your obedient servant,

WILLIAM ANDREWS, M.D.

DR. LETHBY'S CASE OF POISON- ING WITH OXALIC ACID.

To the Editor of the Medical Gazette.

SIR,

I AM disposed to think that the following case presents peculiarities which may give it an interest to some of your readers. I therefore place it at your disposal, and have the honour to be,

Yours, &c. &c

W. LETHBY, M.D.

12, Tredegar Square, Oct. 7, 1844.

An unmarried female, named Rebecca Pentland, aged 22, of previously good health, had, on Saturday, Sept. 28th, a quarrel with her lover respecting another of his mistresses, and, in a fit of jealousy, after he had left her, she took oxalic acid, and destroyed herself: she was found, on the following morning, dead in her room. My friend Mr. Garrett was sent for, who made a post-mortem examination of the body—removing the stomach and its contents, although he had great difficulty in so doing from the corroded and softened condition of that organ.

These he brought me to examine. The stomach was very much blanched, except in two or three places, where there were small black spots, as if blood had been effused and acted upon

by the poison, and here and there a blood-vessel might be seen ramifying, with its contents similarly blackened. The tissue of the stomach was so softened and disorganized that it could scarcely be handled without tearing; indeed, at the cardiac end it was reduced to a pulpy or gelatinous consistence, and had numerous perforations in consequence.

The contents, which had been saved in a tumbler, amounted to about six ounces in quantity; the fluid was of a dark colour, like porter, and contained very little solid matter; it was strongly acid, and, on being tested, was found to contain about three drachms of oxalic acid.

REMARKS.—It has been doubted by some authorities whether oxalic acid has any corrosive action on the stomach. Dr. Christison, I think, only mentions one case in which he found the stomach perforated after its exhibition; and Mr. Taylor remarks that in his experiments on animals, and from some few observations on the human subject, he has found nothing to bear out the view that perforation is a common effect of the action of this poison. This case, however, is sufficient to shew that softening and perforation may take place, and in a medico-legal inquiry it is proper and important to bear the fact in mind.

NOTICE

OF THE

CRYSTALLINE FORM OF CARBONATE,

AND DISCOVERY OF THE

OXALATE OF LIME IN THE URINE OF HERBIVORA.

BY DR. GOLDING BIRD,

Assistant-Physician to Guy's Hospital.

(For the Medical Gazette.)

THE study of the healthy and pathological conditions of the urine of the lower animals, especially of those which are exclusively herbivorous or carnivorous, promises to throw much light upon the nature and treatment of analogous changes occurring in the renal secretion of omnivorous man. Although it is a difficult task to procure the urine of the carnivora, yet from the ordinary domesticated herbivora there would be no difficulty in

collecting the secretion in abundance. I venture to make these remarks in the hope that some of our professors of veterinary medicine may be induced to turn their attention to this subject; for a chemical and microscopic examination of the urine of the horse or the ox alone promises to afford much important information on some points of humoral pathology. I know of no mode so likely to obtain a satisfactory answer to the much-litigated question of the pathological relation existing between urea and uric acid, as the study of the urine of healthy herbivorous animals. The popular theory of the day, propounded by Professor Liebig, is, as is well known, that a low amount of oxygenation going on in the system causes uric acid alone to result from the destructive metamorphosis of tissues, whilst, if an ample supply of oxygen occurs, the acid is wholly or partly converted into urea; oxalic acid being regarded as a morbid product, the result of an access of oxygen insufficient to change the uric acid into urea; being a sort of transition stage from the former to the latter. Urea exists in the urine of the horse with an abundance of hippuric acid, but no uric acid. I am not aware that oxalic acid had been detected, prior to my noticing the fact which forms the chief subject of this communication. It would be very interesting to ascertain whether, in a horse hardly worked and kept without food for a few hours, as a quickly-driven post-horse, uric acid ever appeared, or oxalic acid became increased in quantity. The microscopic examination of the urine of the lower animals will, in a pathological sense, be, as in the human subject, of greater or at least equal importance with the chemical examination.

A short time ago, I had some urine collected from a horse which had remained in the stable unworked all day. I desired my groom to collect it in a large cylindrical glass vessel, and take every care to exclude all dust and dirt.

This urine was yellowish-brown, almost syrupy in consistence, had a strong smell of the stable, and was alkaline to red litmus-paper. It was turbid from the diffusion of a powder which, by repose, subsided as a fawn-coloured copious deposit. The urine being decanted and mixed with hydrochloric acid, effervesced violently, and in a

few hours became actually full of beautiful crystalline masses of *hippuric acid*, which required many washings with water, and one crystallization from dilute alcohol, to become nearly white.

The deposit was washed with water until it lost nearly all odour, and a portion was submitted to microscopic examination. The great mass consisted of myriads of round transparent bodies, gritty to the touch, and resembled completely spheres of glass. These were very difficult objects to define, whether by refracted or reflected light, on account of their refracting light to a focus like spherical lenses. When allowed to dry, these bodies retained their transparency. On the addition of a drop of acetic acid they dissolved with violent effervescence, and consisted, indeed, of carbonate of lime. When the spheres of carbonate of lime were immersed in Canada balsam between thin plates of glass, they exhibited a beautiful structure, which was not previously visible, each being made up of minute needles radiating from a common centre, like some zoölites—a form peculiarly interesting, in relation to the analogous acicular structure of the dumb-bell oxalate, discovered, three years ago, by myself in human urine. On examining the spheres of carbonate in the balsam with polarized light, they presented the same exquisitely-beautiful phenomena which are exhibited by the crystalline lenses of fishes, each shewing a set of beautifully-coloured rings, traversed with a black cross. These formed altogether the most interesting objects for the microscope I have ever met with.

The spheres of carbonate varied greatly in size, ranging from mere points up to $\frac{1}{2000}$ th inch in diameter. I was greatly surprised to find in the deposit from this urine an abundance of octahedral crystals of oxalate of lime, far exceeding in size any I have ever found in human urine. To examine them with advantage, the deposit from the horse's urine should be digested in acetic acid, by which the spheres of carbonate, and a few prisms of triple phosphate, are dissolved. On adding boiling water to the solution, a crystalline deposit of oxalate of lime collects at the bottom of the vessel. This consists of crystals of the same

perfectly octahedral form as those met with in the human subject; consisting of four-sided pyramids placed base to base.

Some few of these crystals presented a form I have never before seen, being short four-sided prisms having each extremity surrounded by a tetrahedral pyramid.

The oxalate of lime in the horse presents a light-amber colour, whereas in man the separate crystals are invariably colourless; the largest I observed possessed a magnitude of $\frac{1}{150}$ inch. On pressing them between plates of glass they readily split into smaller and tolerably regular octahedral fragments. They could only be preserved dry for examination, for in balsam they became nearly invisible.

What is the source of this oxalate? Is it, as in man, a result of mal-assimilation of ingesta, or of the effete elements of tissues? Can it be traced alone to *rumex acetosa* which abounds in most hay? These are questions of importance, not only from their physiological interest, but from the bearing they may possibly have upon the treatment of oxaluria in the human subject.

Myddelton Square, October 1844.

ACESIUS:

A SURVEY OF THE ETHICAL RELATIONS OF
MEDICINE.

By C. F. H. MARX, M.D. &c.

(For the *London Medical Gazette*.)

[Continued from p. 16.]

TO GEORGE CHEYNE,—

During my sojourn in England I found the Quakers so exceedingly obliging, that I have no hesitation in asking you, who belonged to that respectable community, and exerted yourself so much in the cause of dietetics*, who was the author of the temperance-thermometer here appended†. I am extremely curious to ascertain whether the inventor lived prior to 1743, the year in which you died, or at a later period, and you first heard of it in that place where there is neither summer's heat nor winter's cold. As I have some thoughts of writing a treatise on this

very useful instrument, and make it a rule to treat subjects of the kind with special accuracy, you will I trust be disposed to pardon my present importunity.

True, your country possesses Father Mathew, who, by the influence of his word, and, as it appears, by the distribution of his medals, has accomplished so much that, in my opinion, he needed no other instrument than his own pure intentions; probably a good end may be attained in other places too by these same means. A strikingly obvious proof acts most powerfully on the masses; and who knows better than yourself, that the aphoristic sayings of the school of Salerno have done more service than all the rest of the detailed and elaborate works written on hygiene?

There are two things which I highly prize in you, and which suffice to beget confidence both in your character and in your judgment, namely, your decided aversion to personal disputes*, and your truly just and rational commendation of water-drinking†. To the incidental remark, that fasting contributes to cheerfulness, I no less willingly subscribe‡.

When once I come to express my sentiments on the subject of dietetics, my rules for passing happily through life shall consist in a very few propositions. Health I should consider as a virtue, serenity of mind as a duty: I would show that disgust at being sick cannot be impressed too deeply on the mind; for sickness, which is the negation of health, is not only an ob-

* Account, p. 9. I heartily condemn and detest all personal reflections, all malicious and unmannerly turns, and all false and unjust representations, as unbecoming gentlemen, scholars, and christians, and disapprove and undo both performances, as far as in me lies, in every thing that does not strictly and barely relate to the argument.

† Ibid. p. 21. I firmly believe, and as much convinced as I am of any natural effect, that water-drinking only will preserve all the opulent healthy from every mortal distemper, and that a diet of milk and seeds, with water-drinking only, duly continued, and properly managed, with proper evacuation, air, and exercise, is the most infallible antidote for all the obstinate diseases of the body, and distempers of the mind, so far as it depends on the body, the present state of things will permit; and that it will cure every disease in the body, curable, and will render the distemperature of the mind more tractable; and that, at all events, it will make both more tolerable than they can possibly be otherwise.

‡ Ibid. p. 50. The times of abstinence is one reason of the cheerfulness or serenity of some Roman Catholic and southern countries.

* Dr. Cheyne's account of himself and of his writings. London, 1743-8.

† See scale, bottom of next page.

stacle to, but a belying of, destiny. The *valere aude** I would propose as a general form of salutation.

Be not uneasy, most honoured doctor, lest I shall require too much; I well know, it is easier to ask questions than to answer them, easier to give precepts than to follow them. To recommend temperance to the maiden in the dance, to the young man at the banquet or in love, to the daily labourer at his work, were a vain and thankless office: to

advise the imprisoned captive to take exercise in the open air would appear like mockery.

I am free to acknowledge that rigorism in admonition and prohibition is, generally speaking, carried much too far. My endeavour would be confined to this: to expose and proclaim the simplest means; to be always serene in mind; to admit in the body no accomplice but a friend, and if necessary, to put life upon the saveall.

* *Sapere aude*: Hor.—ED.

		Suicide.	Death.	Gallows.	

It must be candidly confessed, that most persons are unhappy, because they are afraid of the possibility of mishap; they struggle too little against it, they take whatever occurs in too unfavourable a light, and look not at the good side of the thing.

The full and complete idea of Fortune seems to those palpitating with anxiety so uncertain and so suspicious, that they beg it may not be called up. They reflect not that Fortune * aids the brave; by Fortune I understand self-confidence accompanied with prudence. Complaints attend almost every occurrence. People laugh at the flagellators who mangle their bodies on the tombs, and weep at the experience accumulated on the graves of times gone by. As beggars hawk their sores in begging, so do they draw consolation from their inward wretchedness.

But aid is to be sought in quite a different quarter. Let every man strive to be master in his own house, that is, in his own person; let him never cry back, as sportsmen say—never be cast down. Let serenity of mind be sought in intercourse with universal nature, with man and with books†; and the purest enjoyment be preserved as a grain of seed, that it may spring up in days of tribulation. The saying that man's fate is his stomach, is perfectly true: good race-horses take but little food. The "death in the pot" lies not in the substance of the pot, in the lead or copper vessel, but in its contents: whoever has the pot filled with dumplings, &c. &c., should not wonder if his heart also become too full in time.

Physicians should not weary of giving currency to the leading principles of dietetics. By so doing they essentially assist in the goodly work of strengthening life in its fundamental conditions,—which is tantamount to prolonging it.

[* *Audaces Fortuna juvet.*—ED.]

† Here our author either had in his mind the stanza or the idea that prompted the stanza which is found under some of the portraits of Goethe. Here it is for our German friends:

Liegt dir Gestern klar und offen,
Wirkst du kräftig Heute, frei,
Kannst auch auf ein Morgen hoffen
Das nicht minder glücklich sei.

MEDICAL GAZETTE.

Friday, October 11, 1844.

"Licet omnibus, licet etiam mihi, dignitatem
Artis Medice tueri; potestas modo veniendi in
dubium sit, dicendi periculum non recuso."

CICERO.

THE MEDICAL PROFESSION BILL.

EDUCATION CLAUSES, RESTRICTIONS ON
THE GRANTING OF DEGREES, THE DEGREE
OF BACHELOR OF MEDICINE.

THE 19th clause of the bill provides that the several Colleges, viz. the Colleges of Physicians and Surgeons of England, those of Scotland and those of Ireland, shall from time to time, and when required by the Council of Health and Education, prepare and lay before the said Council a scheme or schemes of study, and particulars of the examination to be gone through by all persons applying to such Colleges respectively for letters testimonial as physician, or surgeon, or licentiate in medicine and surgery, and of the fees to be taken for examination and admission into the said several Colleges respectively; and the said Council shall be empowered to make from time to time such changes in any of the schemes so laid before them as to the said Council shall seem expedient; and the said Council shall endeavour to procure, as far as is practicable and convenient, that the qualifications and fees for the said testimonials shall be uniform, according to the nature thereof throughout the said united kingdom.

This clause obviously contains the elements of much good. The Council of Health must necessarily be composed of the most distinguished men in the profession, however they are chosen, from whatever quarter they are chosen, and they will doubtless feel it incumbent on them to exact a respectable extent of education, &c. from the candidates of every class and denomination. We almost wish that the paragraph which is conditional had

been imperative; that instead of the Council *endeavouring* to procure, as far as is practicable and convenient, that the qualifications and fees for the said testimonials shall be uniform, it had been directed that the Council should observe that the qualifications and fees *were* uniform. We take it, that with regard to the propriety of having the qualification uniform there can be no question: that the respective education of the physician, surgeon, and licentiate, ought not to differ in England, Scotland, and Ireland. As to the fees, we are in considerable doubt: England is a rich country, Scotland and Ireland are comparatively poor. It is not unusual in England for young men brought up to the medical profession to be men of a certain monied independence; this in Scotland, and we presume in Ireland also, is very, very, rarely the case, yet are the army and the navy, and the East India Company's service, furnished with many of their most active and intelligent medical officers from Scotland especially. Now, were the fees in Scotland assimilated to those of England, the expense would be too great; and then, were the English fees to be brought down to the level of those of Scotland, the English teachers would suffer: the expenses of living, to a professional man in London, are, at least, twice as great as in Edinburgh, Glasgow, or Aberdeen; if he has a somewhat numerous family to bring up, they are probably three times as great.

The 20th clause is also highly proper; it enacts that no University of the united kingdom shall grant degrees to any person unless he shall have matriculated and duly attended the courses of lectures prescribed during at least two years next before the granting of the degree, and unless he shall have undergone examination, and been found duly qualified. We believe that all the

Andrew's?) have now abandoned the practice of selling degrees in Medicine; this clause will effectually prevent its ever being revived; and in conjunction with the 16th clause, which makes a foreign degree, unless obtained after one year's residence at the University which grants it*, of no account, it will render access to the higher grade of the profession difficult—indeed, this grade will only be accessible in one way, viz. the having attained to 40 years of age, satisfying the College of Physicians of England that the preliminary and professional education had been liberal, and standing the test of examination.

Clause 21st is a manifest departure from the principle of uniformity for which the Bill has been commended. Universities of the united kingdom are to have power to grant the degree of Bachelor in Medicine to their own students who shall have attained the

* It will doubtless strike some of our readers, as it did us, to ask wherefore a less term of residence at a *foreign* university should be required than at an *indigenous* one? If one year at Giessen be enough, ought not one year at St. Andrew's to suffice? or if two years at St. Andrew's be thought not too many, why not the same number at Giessen? Thereby hangs a tale,—there are always so many wheels within wheels in the history of human action, that it is often difficult to discover the one which gives motion to the rest. We think we can follow the impelling power here however: the academical and extra-academical teachers of Edinburgh had a grave difference some years ago, which led to a total rupture and separation between them; to the extent even, that the pupils of the extra-academicals did not graduate at Edinburgh, where they *had studied*, but—at St. Andrew's, where they *had not studied*!

At a particular season of the year a certain extra-academical gentleman, a kind of agent for the University of St. Andrew's, used to appear wending his way at the head of 20, 30, and even 50 and more, of the extra-academical students of Edinburgh, towards the shores of the Firth of Forth; there he took shipping for St. Andrew's; all things were in readiness for the examination; the young men were found duly qualified, and within a week the party reappeared from Fife, the juveniles with their diplomas of M.D. in their pockets, and the agent with a new degree of *L.S.D.* in his. One year at a home University would not suffice to keep the stream running the right way; two may; and yet we are not sure of that: two years of extra-academical study at Edinburgh, and one of Collegediscipliniet Giessen or Erlangen, with an opportunity of seeing the world, &c. &c. the whole guaranteed at less than the academical rate,—we should not wonder that the long-headed agent of the St. Andrew's University, as agent for Giessen or Erlangen, would be found a match for the framers of the bill yet!

age of 22 years, which degree, its possessor having been examined by the Royal College of Physicians of England, Scotland, or Ireland, or by the Faculty of Physicians and Surgeons of Glasgow, will entitle him to registration by the Council of Health and Education as a Licentiate in Medicine and Surgery. One man will therefore register as a licentiate of medicine on the strength of an examination successfully stood before the examining body of one of the Royal Colleges of Physicians and Surgeons, another on the strength of his Bachelor's diploma and examination before a College of Physicians only. There is probably no great harm in this, but it makes distinction, and it renders the machinery more complicated than it needed to have been. This will be the entrance to the profession of which men of what is called *connection* or *family*—if such words can be used in reference to our truly noble but little considered profession—will avail themselves; it is probably a door left purposely open to them.

Having got thus far with the bill, we pause to make one statement which we think not unimportant to certain interests. Thus far we see the Council of Health and Education, and the several Royal Colleges, paramount; the Universities, which had hitherto been supreme, appear to us, and as we understand the bill, to be thrown altogether into the shade. Unless a student inclines to take a Bachelor's or a Doctor's degree in medicine, he will have no connection with his alma mater save and except as his nurse; the University—of Edinburgh, to select a particular instance—will become a mere nursery to its Royal Colleges of Physicians and Surgeons. The great body of the profession, in time to come, and as intended by the bill, will probably not take the degree of either bachelor or doctor in medicine, but of licentiate in medicine and surgery; and

this they will obtain, not from the University, but from the associated Colleges of Physicians and Surgeons. The Scotch Universities will sink into mere schools; the professors, save and except through their connection with the College of Physicians, or the College of Surgeons, will be simple teachers. It strikes us that they thus appear shorn of some portion of their dignity and honour by the provisions of the bill. The student of the University has hitherto been accustomed to look up to his professor not only as his teacher, but also, in some sort, as his patron, as the chief under whose certificate of competency he takes his place in the world. We heard much more of the presence in London of the President of the Royal College of Surgeons of Edinburgh, than of any representative of the *Senatus Academicus* of the College of James the Sixth, during the period when the bill was expected to be laid before Parliament. We own that we have a certain affection for our old University; and we should not be pleased to see it vailing the pennon to either College of Physicians or College of Surgeons. Doubtless the *Senatus Academicus* of the Scotch Universities understand their own interests, and will feel it their duty to look narrowly into the general bearing of the new Medical Bill, not only on their pecuniary interests, but on their dignity and consideration. The revenue they had as examiners will cease, at all events; it will flow to the coffers of the Colleges of Physicians and Surgeons; and to be poor in Great Britain means to be powerless. If the Universities have not seen the thing in this light, let them look to it closely.

THE LAUDATION OF THE SOCIETY
OF APOTHECARIES BY TOWN AND
COUNTRY PRACTITIONERS.

SOME few months ago, upon the appearance of the "Statement by the So-

ciety of Apothecaries on the subject of their administration of the Apothecaries' Act," we took occasion to animadvert upon what we believed to be an undue assumption of credit to themselves by that body, for the exertion of an influence of a highly beneficial kind on the progress and present state of that member of the medical profession in this country who is commonly spoken of under the title of "the general practitioner." The worshipful Society appear to have been taken at their word, however, by the majority of the meetings of medical men that have been held throughout the country, for the purpose of considering the Medical Bill: a beneficial influence exerted by the Society of Apothecaries, upon the state of the medical profession, has been all but uniformly prominently avowed.

We are still disposed to take a different view of the matter: we believe that the Society of Apothecaries have had no special influence whatsoever on the state and education of the medical man. The improvement which we remark is not alone conspicuous in the country where the worshipful Society holds sway; it is quite general; it has extended over the sister countries as well; indeed, over the whole of the Continents of Europe and North America. Had we in England alone made progress, and the people in Scotland and Ireland, in France, in Germany, and in the United States of America, remained in matters medical as they were before the eventful year 1815, doubtless there would have been strong grounds for suspecting that the Apothecaries' Society had been at the bottom of the undeniable improvement which medical education has undergone in the course of the last quarter of a century. But, seeing that the advance has been quite general, that it has been as extensive as letters and civilization, we, for our part, are not disposed to view the worshipful

Society in any other light than as bound to the car of human improvement and dragged on with it, not as hastening its progress. It is the general extension of knowledge that has made a larger amount of special knowledge in the medical man necessary, and no enactment of the Apothecaries' or any other Society. We are disposed to go farther than this; we do not hesitate to say, that we view the influence of the Apothecaries' Act of 1815 as having been hostile in many respects, much rather than advantageous, to the progress of true medical science and the best interests of the healing art. It has associated the *profession of medicine* in the public mind with the *traffic in drugs*, to the degradation much more than the elevation of the medical man in the social scale; and then its provisions in regard to the mode in which the practitioner acquired a legal claim to remuneration, led to a system of drugging of such unpalatable magnitude, that the better informed members of the community have finally rebelled against it, whilst the ignorant and the credulous have thrown themselves into the arms of homœopathy, and hydropathy, and empiricism in fifty different shapes, by way of finding refuge from it.

Another view of the case is this:—If the Act of 1815 has done all the wonders which general practitioners are at this time so ready to ascribe to it, how comes it that the very existence of their branch of the profession in its connections with the labouring classes is now threatened by crowds of uneducated and unqualified men in the shape of chemists and druggists? These men are actually disputing the field with the licentiate of Apothecaries' Hall, at this moment, in every town in England, and in many instances are taking the bread from between his teeth. The Act of 1815, in fact, is no protection to the educated practitioner; it is still

less, if that be possible, a protection to the community: the Act is a nullity for every useful purpose, both as regards the public and the profession. Its restrictive clauses have still been found inapplicable where they ought to have been most efficient; they have neither enabled the Society of Apothecaries to get at the practising chemist and druggist, nor at the bare-faced empiric; they have only let loose the dogs of the law effectually at the throat of the man of some standing, occasionally the graduate of a Scotch University, or member of a Scotch College of Surgeons—as good a man at least, and of as liberal education as he at whose instance the Society was moved to prosecute, or as any one in the body by which he was proceeded against.

The Act of 1815 did mischief in another and indirect way: it compelled the student to select not the place where he could obtain the best education at the least cost, but the place where he could obtain the education which would secure him a title to live at peace when he settled himself down as a practitioner. The tendency of the Act has obviously been to force the student from the quiet and application and economy of such an University as that of Edinburgh, or Glasgow, or Aberdeen, with its complete courses of instruction on every branch of medical science, into the noise, and dissipation, and extravagance, of the metropolis, where such monstrosities as lectures three times a week, and between 8 and 9 o'clock in the evening, on some of the most momentous sections of medical lore, are still exhibited and still endured. London as it used to be twenty years ago—a great finishing school of surgery—was very well; no one who knows aught of the habits and lives of medical students, and of the temptations to which they are exposed, does not know that it is most disadvantageously circumstanced for the seat

of schools for elementary instruction in medicine. But had Edinburgh or Glasgow or Aberdeen, had Hippocrates and Galen and Avicenna, Harvey and Sydenham, Haller and Cullen, for its professors, the direct tendency of the Apothecaries' Act has been to keep their benches bare of students.

The Apothecaries' Act has done yet further mischief: the system of examination pursued by the Court of Examiners of the Hall has been such that it has become imperative on every man who would secure his certificate there, to prepare himself especially for that examination by submitting to the degrading process of grinding; diligence during the whole period of studentship does not suffice; the test is of a kind that cannot be met by that; the Society has fostered into existence a set of men "who rather prefer the student at the end of his third winter session, who knows nothing, to him who knows something;" the former he is aware must rely upon him, and will be attentive to the cramming that suffices to bring him through; the latter is apt to rely a little on himself, and not enough on his grinder, and so between the two he is apt to make shipwreck.

We are not yet at the end of our bill of impeachment: the Society of Apothecaries' mode of administering the Apothecaries' Act has had this other ill effect. It is expressly enacted that the Society shall provide *apothecaries*, whose duty, as specified by the Act, it should be "carefully and accurately to dispense the prescriptions of physicians with pure and unadulterated drugs." The Court of Examiners of Apothecaries' Hall have only been ambitious to provide the community with highly-educated practitioners; a condition which the progress of the times would have required and accomplished without them. They have left the professional man, and the wealthier public, to the mercy of

shop-boys in the important matter of dispensing, and they have not been able to protect the labourer and the artizan from being practised upon by men who, though they may be skilful in discriminating drugs, and able as chemists, know no more of physiology and the practice of medicine than the cow-leech and the village farrier.

MOVEMENT IN THE PROFESSION.

IN the resolutions and speeches at the professional meeting held at Liverpool on the 2d inst., Dr. Jeffreys in the chair, we discover considerable shades of difference from the line of argument and objection that has now become trite and barren. Dr. Freckleton moved the first resolution, expressive of satisfaction "that ministers should have introduced a bill into parliament having for its object the better regulation of medical practice throughout the kingdom." Dr. Sutherland, in moving the resolution expressive of "regret that no restriction on irregular practice should have been provided by the substitution of measures more efficient in their operation than those contained in the acts proposed to be repealed—which acts, although they may not have been of sufficient power to remedy the evil, nevertheless, admit the sound principle that the practice of uneducated persons is contrary to law"—took occasion to refer to the charter of the College of Physicians, and the Apothecaries' Act, in the spirit of both of which irregular practice was considered as contrary to law. It was proposed by the new bill to repeal all charters which imposed restrictions on the practice of medicine—to place the educated on the same footing with those who had received no education at all, and for that they had a right to seek a remedy. It was unnecessary for him to argue that men intended for the medical profession must be men of education; the amount of knowledge they required was greater than for any other,—there was scarcely any branch of knowledge they did not require; and the principle that there should be a distinct body of men for that purpose had always been recognized. During the examination before the House of Commons it was stated to be almost impossible to put down illegal practice by the present act, on account

of the expense, but the circumstance of it being deemed necessary to suppress it showed it was an evil. Sir James Graham had stated the impossibility of putting down quackery, but he believed it could be accomplished if proper steps were taken in reference to it. The new bill itself admitted irregular practice to be an evil, for it excluded irregular practitioners from the army and navy, and from all public medical offices. If a practitioner were found not to be registered, let him be taken before the magistrate, and quackery would soon be put down; as far as law could reach it, that course would be most effectual.

The following excellent and temperate memorial to Sir James Graham was agreed to:—

To the Right Honourable Sir James Graham, Bart. Her Majesty's Principal Secretary of State for the Home Department. This Memorial agreed upon at a Meeting of the Medical Profession of the Town of Liverpool, held at the Medical Institution on the 2d of October, 1844,

Sheweth—

That your Memorialists hail with satisfaction the introduction into Parliament of a "Bill for the better Regulation of Medical Practice throughout the Kingdom." That they have given a careful consideration to the said Bill, and beg respectfully to submit to you their opinions on the same.

That inasmuch as the restrictions on unqualified practice as they at present exist in the several acts and charters proposed to be repealed in the first clause of the said Bill, have been local in their application, and have thereby frequently been injurious to well-educated members of the profession; and especially as they have never proved themselves to be a sufficient protection to the public against ignorant and unskilful pretenders, your Memorialists think it quite necessary that these acts and charters should be repealed and annulled.

That nevertheless these acts do acknowledge as a principle in law, that persons not duly qualified shall be prohibited from practising under certain penalties, and if they shall be repealed without at the same time substituting a *more efficient prohibition* against irregular practice; your Memorialists con-

sider this giving up of a sound principle as pro tanto legalizing the practice of unqualified persons, as tending to lower the dignity of the medical profession, and at the same time taking away from the profession its legitimate rights, while it withdraws all protection from the public.

That as the medical profession is at present constituted there exist registers of all qualified practitioners in the united kingdom, some of which are from time to time published; and that instead of these it is proposed to have one general registration, a measure of which your Memorialists cordially approve, as lying at the basis of all effective legislation on the subject.

That, by existing laws or usage, no unqualified practitioner can or does hold any medical office in infirmaries, dispensaries, poorhouses, or prisons; or in the army, navy, or East India Company's service, and that considering the proposed registry as a test of qualification; your Memorialists approve of it as a means of excluding as heretofore all unregistered and unqualified persons from such public medical offices.

That, as it is fully conceded by the Bill that it shall be unlawful for any unregistered person to practise in certain departments and public offices, your Memorialists know no valid reason why the same principle should not be fully carried out so as to render it unlawful for any one to practise medicine and surgery in any part of the United Kingdom, without being duly qualified and registered; while they are of opinion that great good would follow if the bill declared all such irregular practice subject to a penalty similar to that which the Bill inflicts on all unqualified persons practising in public offices, but recoverable by a summary process.

That your Memorialists are of opinion that a measure founded on the proposed registration may be devised, better calculated than the laws now existing to protect medical men as well as the public against unqualified practitioners.

We have farther notice of a meeting of the medical men of the Borough of Devonport and Stonehouse, Mr. Tripe in the chair, which was respectably attended, and at which the usual resolutions were passed.

We have also notice of a large and respectable meeting of the Gloucestershire Medical and Surgical Association, held on the 4th inst.—Dr. Hardwicke Shute in the Chair—the resolutions passed at which are all more or less in favour of the bill—that is to say, they do not fly in the face of the Government measure altogether, but begin by approving of each principle, and then propose amendment; they agree, and then they differ. The 1st resolution is to this effect: "That this meeting desires to express its high satisfaction that the Government has at length brought the state of the medical profession under the consideration of the legislature, and is fully prepared to assent to the general principles of the measure recently introduced by the Right Hon. the Home Secretary."

The 2d resolution is the following: "That while the proposed establishment of a Central Council of Health and Medical Education appears likely to promote the respectability and protect the interests of the medical profession, this meeting is of opinion, that the constitution of that Council, as laid down in the Government bill, needs further consideration; and more particularly as regards the relative proportion of Councillors to be elected by the profession, and that the measure would be greatly improved by permitting the medical practitioners of the provinces to elect the two representatives whom Sir J. Graham has proposed to appoint from the rural districts."

The 3d says: "That as one of the most important features of the bill is the abrogation of existing penalties on unlicensed practitioners, this meeting admits that, in the present state of public opinion, any direct legislative interference with unqualified practitioners would not be unattended with difficulties; but has, nevertheless, reason to believe that these difficulties have been much over-rated, and that if fairly met, they will not be found to be insuperable, and, therefore, that the principle of protection against unqualified pretenders may be more extensively applied than is apparently contemplated by the bill."

The 4th: "That this meeting would respectfully submit to the consideration of the Government, the propriety of such indirect discouragement of illicit

practice as would be effected by abolishing the present obnoxious system of stamped and patent medicines, and by prohibiting, under severe penalties, the advertisement of secret remedies, now carried on to an extent alike injurious to public health, and offensive to public decency."

There are various ways of being pleased, and various modes of expressing dissent. We have done that openly which our brethren at Gloucester have done more covertly. Have our friends there had the assistance of any associate of the celebrated society instituted by Ignatius Lloyola, in drawing up their resolutions?

It is long since we have heard anything of the

BRITISH MEDICAL ASSOCIATION,

with Dr. Webster at its head; it is alive, however, and sends us what follows.

At a recent meeting of the Council held to take into consideration the Medical Bill of Sir James Graham, it was unanimously resolved:—

I. That the Bill is exceedingly defective and illiberal in many respects, and if it should be passed by the legislature in its present state, would be highly injurious to the public and the profession.

II. That it nevertheless recognises and contains several important provisions founded on the great principles of Medical Reform, for which the British Medical Association has been strenuously contending since 1836; and that it would be inexpedient and unwise recklessly to oppose the entire measure, because it is defective in some respects, and illiberal in others.

III. That the chief defects of the Bill are:—

1st. The want of the true representative principle in the election of the ruling bodies in the medical corporations.

2d. The absence of any provision for uniting the medical profession into *one body or faculty* of medicine, upon the acknowledged principle that medicine and surgery, with their various subdivisions (for the public convenience) are but parts of *one science*, which can only be effectually taught as a whole.

3d. The want of *all effective protection* to the public and the profession,

against the evils arising from the practice of unqualified persons.

4th. The unjust and illiberal constitution of the proposed Council of Health and Medical Education, in which the great majority of medical practitioners would have no voice, while the influence of the Home Secretary and the Government would be overwhelming.

5th. The obvious effect of the Bill, in connection with the charters recently granted to the Colleges of Surgeons, would be to degrade general practitioners, and improperly to elevate pure surgeons and physicians.

6th. The omission of any summary and inexpensive mode of enforcing penalties (such as by information before two of Her Majesty's Justices of Peace), against those persons assuming medical titles, or falsely pretending to be on the proposed register.

7th. The absence of any defined method of sufficiently making known to the public the names of registered practitioners.

IV. That the features of the bill which the Council recognize with satisfaction, and which if properly carried out would be beneficial to the profession as well as to the community, are the following.

1st. The appointment of a general Council of Health and Medical Education, which if justly constituted and judiciously worked, implies a greater concern for the public health than government or parliament have hitherto evinced.

2d. The legitimate connection for the first time of the profession with the government, and thereby much readier access to Parliament and to the ministers of the crown, through the Secretary of State for the Home Department.

3d. The general superintendence of medical education, with uniform tests of qualification for practice.

4th. The erection of the Council of Health into a court of appeal against any oppressive or unjust acts which may be committed by the medical corporations, and which have hitherto passed with impunity and without redress.

5th. The general registration of all qualified practitioners.

6th. The right to practise in all parts of Her Majesty's dominions, after being duly qualified and registered.

7th. The provision against the as-

sumption of medical titles by unregistered practitioners.

8th. That none but registered practitioners can legally recover charges for medical or surgical advice, attendance or operations, or for medicine prescribed or administered.

V. That the Council having found from previous experience, that all former attempts at medical legislation by individual members of Parliament have failed, and this Association having by deputation and correspondence strongly urged upon Sir James Graham the propriety of Government undertaking the conduct of a bill to regulate medical qualifications and practice, upon liberal and broad principles, are of opinion that no measure would be likely to pass unless introduced by Government, and therefore, that it is the duty of all medical reformers to endeavour to obtain such modifications of Sir J. Graham's bill, that it may be calculated to give satisfaction to the profession, and to confer the greatest amount of benefit on the public.

VI. That any Medical Bill which does not contain power effectually to restrain ignorant and unqualified pretenders from practising the healing art in any of its departments, will be most deceptive and injurious to the community, and most unjust to medical practitioners, who have at much cost of time and money qualified themselves for the service of the public.

Signed, on behalf of the Council,
GEORGE WEBSTER, President.

Exeter Hall, Oct. 7, 1844.

LONDON HOSPITAL.

Hydrocele of the Hernial Sac—cured by external treatment.

JOSEPH BOLTWOOD, a shoemaker, aged 58, came under the care of Mr. Curling, March 25th, on account of a swelling in the left groin. There was a tense tumor, the size of a hen's egg, just below the external abdominal ring, and about two inches above the testis, from which it was quite separate. It received no impulse on coughing, fluctuated indistinctly, and was very tender when handled. The spermatic cord could be traced from the testis to the back part of the swelling. The tumor was defined below, but extended by a broad neck into the inguinal canal. The patient was placed in a dark corner of the room, and the swelling was examined with a candle, and found to be transparent; but its want of prominence, and

small size, rendered this mode of examination very difficult. He stated that the swelling first came about two years ago, after a blow in the groin which he received by running against a post. It came gradually in the course of a month after the accident, and has never since disappeared. He was seized, three days before he came to the hospital, with vomiting, and pain which extended from the tumor into the abdomen; and pain was still felt on pressure in the vicinity of the abdominal ring. He had experienced a similar attack about nine months previously.

Mr. Curling remarked that there was some difficulty in this case in determining whether the swelling was an encysted hydrocele of the cord, or a hydrocele of the hernial sac. He came, however, to the conclusion that the case was a hydrocele of the hernial sac; a piece of intestine or omentum being adherent at the ring, and slightly inflamed, pain being experienced just above the tumor. The pain in this situation, and the diffused character of the upper part of the swelling, induced him to think that it was not an encysted hydrocele of the cord. The patient was directed to apply eight leeches to the upper part of the swelling, and afterwards a cold lotion, to take a dose of castor oil, and to remain at rest in bed.

28th.—The swelling was less in size and not so tender, and he was relieved of the pain in the abdomen. Five more leeches to be applied, and the lotion continued.

April 3d.—The swelling further diminished, and all tenderness removed. A blister to be applied. From this period the swelling continued steadily to decrease, and on the 17th all the fluid had disappeared. On placing the hand on the groin, a distinct impulse, arising from a slight protrusion, was felt when the patient coughed. A truss was applied; this restrained the protrusion, and the patient was discharged cured, without the slightest swelling remaining in the course of the spermatic cord.

Varicocele treated by Compression.

William Coomber, aged 21, a light porter, enjoying tolerable health, though occasionally subject to dyspepsia, came under the care of Mr. Curling, as an out-patient, on the 17th of July, in consequence of suffering from a considerable varicocele on his left side. He had been subject to it for more than nine months. He complained of experiencing pain in the left side of the loins, and an uneasy aching sensation in the testis, which were increased by exercise, and by lifting weights. The scrotum was lax and pendulous, and the left testis was about one-third less in size than the right. He applied to a surgeon six months ago, and was recom-

mended to wear a truss. He wore one of the common description for four or five months, but found no relief from it. He was advised, therefore, to discontinue it, and to use a suspender. He had worn the latter for the last five or six weeks, but the varicocele continued to get worse. The *moe-main lever truss* was ordered to be applied; the scrotum to be sponged night and morning with cold water; the bowels to be relieved occasionally by a mild aperient.

22d.—He had worn the truss constantly for the last six days, and felt greatly relieved, so that he was able to walk about without suffering any uneasiness. The varicocele appeared slightly reduced in size.

August 28th.—The patient stated that he continued to derive relief from the truss, and had become accustomed to the pressure of it, so that it caused him no annoyance. His appetite and digestion were improved, and he had returned to his employment Discharged.

THE PHYSICAL SOCIETY OF GUY'S HOSPITAL.

ON Saturday evening, the 5th instant, the Physical Society of Guy's Hospital, the oldest of all the medical societies established in London, held the first meeting of its 72d session; Dr. Babington, the senior President, in the chair.

The President, in his opening address, alluded to the leading incidents in the history of the society, the successive alterations in its internal arrangements, and the many eloquent and distinguished men which it had numbered among its members, both within and without the pale of the profession, particularly alluding to the eloquence of Thelwall, Drs. Hosack and Currie, and the unfortunate but misguided Robert Emmett, who suffered the extreme penalty of the law for engaging in the last rebellion in Ireland, —all of whom, he believed, had written papers for this society. He dwelt upon the advantages which societies like this produce to all ranks and ages, especially now that they are framed on less comprehensive principles, and confined to members of particular professions, and more especially upon the excellent test they afford to writers, of arriving at the real value of their particular views. Submitted in the form of a paper to such an ordeal as the experience of the older, and the improved scientific knowledge of the junior members afforded, a tolerably correct estimate of the value of every view and suggestion, might be obtained, which was often found less than the original estimate.

A paper by Mr. T. Wilkinson King was then read, containing, amid *multa alia*

some peculiar views on the capillary circulation of the face and head, and its influence on diseases of these parts. The author seemed to regard the circulation in the capillaries as entirely independent of the influence of the nervous system, and solely dependent on position and physical conditions. An animated discussion controverting this notion was elicited, in which Sir George Lefevre, Dr. Addison, Mr. Hilton, and other members, took part, till the hour of adjournment, half-past nine, arrived; when the thanks of the society were voted to Mr. King for his communication, and the President adjourned the meeting, with the announcement that Dr. Ashwell would bring forward the subject of Fibrous Tumors of the Uterus at the next meeting, which will take place on the 19th instant.

MEDICAL ETHICS.

DEATH OF THE REV. DR. ARNOLD.

IN the very interesting memoir of this distinguished scholar, a most affecting narrative is given of the manner and circumstances of his decease. It is my wish, on this occasion, only to draw attention to the conversation between the patient and his medical friend.

Between 5 and 6 o'clock on Sunday morning, Dr. A. awoke with a sharp pain across his chest. He complained of this to his wife, and mentioned that he had it slightly the preceding day. The pain increased, and seemed to pass from the chest to the left arm, so that a suspicion arose in the mind of Mrs. A. of its being an attack of angina pectoris. His sufferings continued severe, although variable as to the degree; and it was evident from the solemnity of his manner, though habitually a devout man, that he had the impression that his seizure was a perilous one. His medical attendant was sent for. At a $\frac{1}{4}$ to 7, Dr. B—, (son of the usual medical attendant) entered the room. Dr. A. was then lying on his back; his countenance much as usual. His pulse, though regular, was very quick, and there was cold perspiration on the brow and cheeks; but his tone was cheerful. "How is your father?" he asked, on the physician's entrance: "I am sorry to disturb you so early; I knew that your father was unwell, and that you had enough to do." He described the pain, speaking of it as having been very severe, and then said, "What is it?" While the physician was pausing for a moment before he replied, the pain returned, and remedies were applied till it passed away. He asked again, what it was? and was answered, that it was spasm of the heart. He exclaimed, in his usual manner of recognition, "Ha!" and then, on being

asked, "If he had ever in his life fainted?" "No, never."—"If he had ever had difficulty of breathing?" "No, never."—"If he had ever had sharp pain in the chest?" "No, never."—"If any of the family had ever had disease of the chest?" "Yes, my father had; he died of it."—"What age was he?" "Fifty-three."—"Was it suddenly fatal?" "Yes, suddenly fatal."—He then asked, "If disease of the heart were a common disease?" "Not very common."—"Where do we find it most?" "In large towns, I think."—"Why?" (Two or three causes mentioned.) "Is it generally fatal?" "Yes, I am afraid it is."

The physician now left the room to obtain remedies, and on his return they were applied. There was a slight return of the spasms, after which Dr. A. said, "If the pain is again as severe as it was before you came, I do not know how I can bear it." He then fixed his eyes upon the physician, who rather felt than saw them upon him, so as to make it impossible not to answer the exact truth; repeated one or two of the former questions about the cause of the disease, and ended with asking, "Is it likely to return?" and on being told that it was—"Is it generally suddenly fatal?" "Generally." On being asked whether he had any pain? he replied that he had none, but from the mustard plaster on his chest; with a remark on the severity of the spasms in comparison with this outward pain; and then, a few moments afterwards, inquired what medicine was to be given;—and on being told, answered "Ah! very well."—The physician, who was dropping the ludanum into a glass, turned round and saw him looking quite calm, but with his eyes shut. In another minute he heard a rattle in the throat, a convulsive struggle,—and animation ceased.

It is very far from my wish to impugn the conduct of Dr. Arnold's medical friend on this great emergency. He might have been a man whom no evasion would satisfy; and direct falsehood never can be justified. I am very far from sanctioning that false delicacy which governs many practitioners in their intercourse with the sick, and by which the peril of the case may be known to the family and friends, but not to the patient, though to him the knowledge is very important, that he may arrange his temporal affairs, and all-important, that he may prepare for eternity. Nevertheless, it appears to me that it would be very sad if the proceedings in the case before us were drawn into a precedent. The symptoms of angina pectoris are so evident, that very few questions are requisite at the moment, and information at all likely to agitate should be sought from friends. Without any previous intimation, who can tell, in a first seizure,

whether or not it is a case of functional disturbance, not one arising from ossification of coronaries, or degeneration of muscular structure? but in either case, *under the paroxysm*, the mind should be kept as undisturbed as possible. Patients usually attach much importance to *spasm*. I do not see the propriety of telling a patient, at the time, that he had *spasm* of the heart, and not that there was "some disturbed action." I cannot see, in such a case, and at such a moment, that it would be requisite to draw from the lips of a patient information as to hereditary tendency, or to tell him that these seizures were usually suddenly fatal. I would rather direct thought to the other side; assure the patient that these attacks, though serious, were often unconnected with organic disease—functional disturbances, frequently recovered from, and sometimes confined to a single seizure. The emotion of a really good man (and there is no question of the piety of Dr. Arnold), when suddenly called to view himself as a dying man—about to depart from his beloved family, about to be severed from things deeply interesting him, his mind taking a rapid and wide glance at the consequences of his dissolution—is already such as to perturb the soundest heart. How greatly must that emotion perplex the movements of an organ previously so disordered or diseased, as to have placed life in the most imminent jeopardy? It is not difficult so to regulate phraseology, that a calming persuasive tenderness shall be combined with fidelity; but in the report, quoted from the memoir, it seems to me that there is a bluntness which fidelity does not require.

W. COOKE.

39, Trinity Square,
Sept. 24, 1844.

FORMATION OF BONE.

M. FLOURENS, whose inquiries on this subject, published in 1842, are so well known generally, has lately made a farther communication to the Academy of Sciences on the subject. M. Flourens maintains—

1st. That bone is formed in the periosteum. 2d. That bone increases by the superposition of the external layers. 3d. That the medullary canal enlarges by the absorption of the internal layers of the bone. The experiments by which he now seeks to demonstrate the first of these propositions were performed upon dogs. In several of these animals a portion of a rib was removed, the bone properly so called only being taken away, the periosteum, detached from it, being left. After several days a small bony nucleus, which increases gradually, and finally connects the two ends, is found in the periosteum, left between the two cut extremities of the rib. The preparations

exhibited shewed this process of preparation in its different phases, and the formation of the new bone in the periosteum; in the first instance, it is now completely isolated, and distinct from the old bone; it is only by its progressive growth that it finally reaches the extremities of the old bone, and connects these with one another. The 2d proposition, viz. That bone grows by the superposition of external layers, is supported by the following experiments made upon rabbits and dogs:—The tibia in several of these animals having been laid bare, the periosteum was divided, and a piece of platinum wire was thrust between the periosteum and the bone, and then bent into the form of a ring. The bone continued to grow, and as it grew, it covered the ring of platinum wire with its new layers. In the same way the 3d proposition was demonstrated by preparations, which shewed that the internal layers of long bones were successively absorbed, and that this successive absorption was the sole cause of the enlargement of the medullary canal. M. Flourens' paper wound up with some observations on the absorption of portions of the bone of one animal, placed in contact with, or inserted into, the bone of another animal. A portion of the rib of a rabbit, for example, put into a hole in the tibia of a dog, soon shews signs of absorption, of erosion, and these are by so much the more decided as the experiment has been continued for a longer time.—*Académie des Sciences*, 30 Sept.

[We have always looked upon the experiments of Dr. Davy and Mr. Gulliver, as related in one of the fasciculi of Pathological Anatomy illustrative of the Pathological Collection at Fort Pitt, Chatham, which may be styled the *converse* of those of M. Flourens, last alluded to, as far more extraordinary. Dr. Davy and Mr. Gulliver found that they could frequently procure the adhesion of a piece of bone of a creature that had long ceased to live—a portion of a human tibia, for example, sawn from a bone that had lain for years in a drawer or cupboard—with the bone of a living animal: a part that had been dried and dead for a dozen years, placed in contact with an analogous living tissue, actually recovered its vitality, and became an integral part of a living animal!—*ED. GAZ.*]

POISONING WITH MORTAR OR QUICKLIME.

A BOY, three years of age, playing in a garden where builders were at work, tasted some slaked lime, and finding it sweet, he ate a considerable quantity. The parents observed him; and having taken a quantity of lime from his mouth and nose, sent for me-

dical assistance. The child was ordered an emetic of ipecacuanha, and after large doses vomited up a mass of grey stuff, like mortar. Almond emulsion was then ordered. The night was restless; the child was feverish, drank frequently, refused food; the lips were of chalky whiteness; the mouth showed several blisters; the belly was hot, and painful on pressure; the alvine evacuations were bloody. A few leeches were now applied to the abdomen, &c. The child at last did well.—*Dr. Lion, in Casper's Wochenschrift*, No. 33.

LECTURES
ON THE
NATURE AND TREATMENT OF
DEFORMITIES,

*Delivered at the Bloomsbury Square
Institution.*

By R. W. TAMPLIN, F.R.C.S.E.
Surgeon to the Institution.

TREATMENT OF TALIPES VALGUS.

THE method for the treatment of valgus, which I have usually adopted, is as follows. When the contraction of the muscles is rigid, both in congenital and non-congenital cases, section must be had recourse to; at least I would advise it. In congenital cases, as far as my observation goes, it is invariably necessary, although the deformity may be slight, and the foot is easily brought into and held in position. We have patients now standing on the books, in whom, from a few weeks after birth, the most careful and constant mechanical means were adopted, and the foot during the time these means were applied was held in position; but the moment the feet were released from the instrument the deformity returned: even after a period of twelve to eighteen months, and where I have since divided the muscles contracted, viz. the peronei and common extensor of the toes, a cure of the deformity has very quickly followed, and all tendency to contraction has subsided. I have operated on a child five weeks old, and after a month's treatment, the foot did not, when taken out of the instrument, return to its malposition. Therefore there is no doubt in my mind as to the mode to be adopted. The operation is unattended with pain, or comparatively so, as the child will take the breast immediately afterwards, and no ill consequences are to be anticipated with the most ordinary care; therefore there is no argument against the propriety of operating. After you have

thus overcome the resistance of the muscles, the placing and maintaining the foot in position at this early age is an easy matter, as you have no additional obstacle or resistance, and the ligaments grow in their natural position; and the muscles are also enabled to act in their normal direction. The overcoming and preventing the contracted condition of the muscles at this early age is of great importance. The mode of operating is as follows. Let an assistant with one hand hold the leg firmly, and with the other adduct forcibly the foot, which renders the peroneus longus and brevis muscles tense. The leg lying on its inner side, the outer side being upwards, you then with the forefinger of the left hand feel for the tendons and also the fibula. You will generally find the tendons raised above the level of the fibula, and a space between them and the bone. You then introduce a sharp-pointed knife between the bone and tendons, with its flat surface to the bone, about an inch and a half or two inches above the joint, to about half an inch in depth, *i. e.* beyond the external edge of the fibula, or as far as your judgment will direct you; turn the knife with the sharp edge to the tendons, and cut them transversely. This is my method of operating, and the one which, I think, you will find the best. You can adopt a plan I have sometimes witnessed, namely, that of passing the knife behind the tendon and cutting from within outwards upon the fibula; this method, however, is less certain, and you run the same risk as in the division of the posterior tibial tendon, of breaking the point of the knife on the bone. As soon as the tendons are divided, a sudden jerk will be communicated to the hand of the assistant, and if both are effectually divided a double jerk will be felt, the one following the other immediately; especially in adult cases. In infants the muscular fibre extends much lower, and this distinct sensation is not felt, although if divided a sense of yielding must be felt. After dividing the peroneus longus

and *brevis* muscles, you proceed to divide the *extensor communis digitorum* and the *peroneus tertius*, which is done in the following manner. Let the patient lie on his back or side, and let the assistant adduct the foot as in the former instance. Introduce a sharp-pointed knife to the inner side of the *extensor communis*, just where it passes over the ankle-joint; pass it beneath these tendons and the *peroneus tertius*, with the flat surface towards the tendon: as soon as you have inserted the knife behind the whole of them turn the sharp edge towards the tendons, depress the handle, and divide them: from their prominent position you will have no difficulty in feeling them, or ascertaining if they are completely divided. You then place a piece of lint on the points of puncture, and secure it with strapping. Bandage the foot from the toes upwards. Let the foot be kept at rest in the horizontal position and (as in the method of treatment of the other cases I have before described,) let it be kept warm: at the end of three or four days you may remove the bandage and strapping, and you will find the puncture healed. You then commence the mechanical treatment, which consists in gradually adducting and depressing the foot, at the same time that you support the arch, so that the new uniting medium becomes stretched at the same time that you are pressing the bones of the foot forming the arch into their normal position. I have found a splint, extending from below the knee to the inner ankle, with a **spring** attached at its extremity, to extend **the length of the foot**, very useful, the spring **having** a soft pad attached, directly opposite and rather beneath the *os-scaphoides*. The splint being well padded, and carefully bandaged on the leg on the inner side, then apply a strap, or adhesive plaster, round the extremity of the spring and the anterior portion of the foot, gradually tightening it as much as the feelings of the patient will admit of: in this way the ankle may be restored with great comfort to the patient, as the pressure and counter-pressure are equalized, and all danger of sloughs from undue pressure avoided. In infants you will find it of the greatest possible advantage. As soon as you have raised the scaphoid bone, and restored the arch, commence the flexion of the foot with Scarpa's shoe, and when beyond the right angle, let the patient have a boot with a cork sole and a support attached, so that he may be enabled to take exercise, at the same time that the ligaments of the foot are gaining strength. In the most severe cases, where the anterior tibial muscle is also contracted, you will find it necessary to divide the tendon of that muscle at the same time, in the manner described in a former lecture; and in severe congenital cases, as represented in fig. 2, p. 36, when

the deformity has been allowed to exist for years without any attempt having been made to relieve it, you will find every muscle surrounding the joint contracted. The following is an instance:—A patient, 15 years of age, was born with this deformity in both feet, and about two years since was operated upon and treated mechanically without relief. Upon examination, the feet presented the appearance represented in fig. 2. The patient was totally unable to walk, from the great pain occasioned when the feet were subjected to the weight of the body. Upon attempting to adduct the feet, the *peronei* and common *extensor* were rendered extremely tense; upon attempting to flex the foot, the *tendo-Achilles* was also tense; and upon an attempt to depress them, the anterior tibial and *extensor proprius pollicis* were also tense, there being the smallest possible amount of motion in the joint, and that of an unyielding character. I therefore proposed the division of the tendons of the whole of these muscles as the only prospect of relief, which was assented to. I first divided the *peroneus longus* and *brevis*, then the *extensor communis digitorum*, and *peroneus tertius*, afterwards the anterior tibial and *extensor proprius pollicis*, and lastly the *tendo-Achilles*. Lint and bandages were applied, and allowed to remain on a week, the patient having suffered no pain beyond that immediately following the operation. At the end of that time I applied one of Scarpa's shoes, and flexed and extended the foot alternately night and morning, so that the uniting medium of each tendon might be acted upon, the foot being adducted the whole time. At the end of three weeks the motion of the joint was restored perfectly, and the patient possessed the power of flexing and extending it at will.

This case is of great interest, as it would appear that the *gastrocnemius* had become contracted from position, the feet being at right angles; and also, that the means adopted were those only which could have succeeded, as the division of one without the others would have effectually prevented, as in fact it had done, the restoration of the feet to their normal position, or the return of the motion of the joint. I have never seen this condition in the infant afflicted with this deformity, and can account for this additional contraction only by the constantly maintained position at right angles. Should you, therefore, meet with such a case, I would advise your adopting a similar plan of treatment.

The time occupied in effecting a cure will vary according to the extent of the displacement and rigidity you may have to contend with. In infants or young children, it will occupy from four to six weeks: in the adult deformities, however,

it will require three or four months of careful mechanical treatment before the bones are brought into their natural relative position: as soon, however, as this is accomplished, the patient will be able to flex and extend the foot with the greatest freedom and without pain, and with the boot and support I have before alluded to, will walk with great ease and comfort. That of the gravedigger was a most severe case of this distortion; previous to the treatment he had in one foot no motion—in the other no available motion of the joint at all, and was ultimately compelled to relinquish his employment, the effort of walking but a short distance occasioning great pain. The moment the feet were restored, he possessed free motion in both feet. Three months, however, after treatment, without any assignable cause (for he suffered scarcely any pain, and none the latter part of the time), he was attacked with acute meningitis, which rendered it necessary to remove the apparatus. Leeches, blisters, and cold lotions, were applied, and doses of calomel given him every two hours: the mouth became affected in the course of forty-eight hours, from which time he slowly recovered. The convulsive twitchings of the muscles, however, remained for a fortnight afterwards. I can attribute this casualty only to his good living, and leading an idle life. The boy was suffering neither mentally nor bodily; but he was in fact highly pleased at his prospect of cure. He left the charity completely recovered. Had any unpleasant result followed, there is but little doubt that it would have been attributed to the operation, and any casualty occurring, which is common to all operations and treatment of every disease, would, as you must perceive, prejudice the charity in its early existence. It will be necessary for the patient to wear a support for at least twelve months, or at least until the arch of the foot is maintained when subjected to the weight of the body. Let him never be without the support at night for some time, following the active treatment, as the more constantly and uninterruptedly the bones are kept in apposition the more speedy and certain will be the ultimate recovery. You cannot be too particular about this point, as by any neglect either on the part of the attendant or on that of the patient or friends, a relapse will certainly be the consequence.

I must now call your attention to those deformities which are considered to be of a compound nature, and which are derived from a union as it were of talipes equinus with either talipes varus or talipes valgus, and are designated by the respective terms of talipes equino-varus, or talipes equino-valgus. I do not myself see the necessity for multiplying terms; but as it has been done by others to distinguish the various forms of the

deformity, it is perhaps as well to adhere to them. By talipes equino-varus will be understood an elevation of the heel from contraction of the gastrocnemius, and inversion of the foot from contraction of the anterior or posterior tibial, or both; the patient walking on the outer and inferior surface of the fifth metatarsal bone. In fact

FIG. 5.

An illustration of talipes equino-varus in its less severe form.

I see no difference in the character of this deformity from varus, excepting in degree. Talipes varus being congenital and non-congenital; talipes equino-varus has this distinction also—the same muscles are contracted. The same treatment is necessary, so that it is useless to enter more fully into the description of this deformity. Talipes equino-valgus, however, presents this difference—that in *true* talipes valgus you find no contraction of the gastrocnemius muscle in infants, although it becomes so from position; in talipes equino-valgus you have the contraction of this muscle; so that it consists in the elevation of the heel or contraction at right angles, combined with a sinking of the arch and more or less eversion of the foot; you have the same anatomical condition of the bones of the foot—this deformity is non-congenital. The cause of talipes equino-valgus is irritation and disease of the brain or spinal chord, producing paralysis of the anterior and perhaps the posterior tibial muscles; the cause is generally attributed to the irritation of teething. The heel is seldom elevated beyond a right angle; the arch of the foot is gone, and the peronei (longus, brevis, and tertius,) as well as the common extensor, will be found contracted; the anterior portion of the

FIG. 6.

An illustration of talipes equino-valgus.

foot everted, and the patient walking on the inner edge of the foot, but more especially on its anterior surface on the ball of the extremity of the great toe, producing, as the patient throws the weight of the body on the foot in walking, a great and constant strain on the internal lateral ligaments, which at times is so weakened and elongated as almost to allow the astragalus to fall out of it, which, if the articular cavity admitted of it, would unquestionably take place: the external lateral ligaments become proportionably contracted, and offer more or less resistance to the restoration of the foot to its right position: here, as in valgus, where this extreme condition of parts exists, the degree of obliquity of the astragalus renders the ankle capable of but very little motion; most frequently you will find paralysis of the anterior tibial muscle to exist. Occasionally, however, as in all cases where paralysis has been the primary cause, you find a partial restoration of the functions of the muscle; there will be also more or less atrophy of the limb, and a reduced nervous vitality of the skin, as well as other tissues. We now come to the

Treatment.—If there is decided contraction, and the foot cannot be completely adducted by the hand, you must have recourse to the division of the tendons,—the mode of doing which, and the precautions necessary to be observed, I have previously fully detailed to you. It will be better to divide the whole of the tendons at one operation; and, after the punctures are healed, to proceed slowly with the mechanical treatment; first directing your attention to the adduction of the foot, and extension of the new connecting matter of the divided tendons: after this is

accomplished, proceed with the flexion of the foot, and as soon as it is brought into the flexed and adducted position, let the patient have a boot with a support attached on the outside of the leg, with a strap passing over the ankle, to hold the foot in position during the time the lateral ligaments are gaining strength; you will also require the raised cork in the sole to support the arch of the foot. If the originally paralysed muscles have recovered their power of action, you may anticipate a perfect restoration eventually, if proper attention be given to keeping the foot in position. If, on the contrary, paralysis of the anterior tibial muscle still exists, you can do no more than remove the deformity, and rest satisfied with the artificial support. The ligaments in this instance will contract, and hold the foot in the proper position, so that the patient will be enabled at times to walk tolerably well in a common boot. In a case I operated upon 18 months since, of a young gentleman, 10 years of age, paralysis of the anterior tibia muscle existed and still exists; there was an extreme relaxation, a looseness of the joint, especially on the internal side, appearing as if the internal lateral ligament was altogether absent. The peronei, the common extensor, and the tendo-Achilles, were divided; which, as a matter of course, both at the time of the operation and for some time afterward, increased the weakness. At the end of twelve months, by continued attention to position, the foot presented a natural appearance; all trace of deformity ceased to exist; and he was able to walk without any support, at the same time feeling a sense of weakness; in the after part of the day he wore a shoe or boot, from which he experienced no inconvenience. There can be no doubt but that if he were to omit the support altogether, the deformity would return, as the balance of power could not be maintained except by artificial support; you cannot, therefore, pay too much attention to this point.

Although I have described *true* talipes valgus as existing without contraction of the gastrocnemius, and talipes *equinus* valgus as being thus distinguished from it, yet I must not have you regard this as an absolute rule, for in the most severe cases of *true* talipes valgus, where there is none or very little motion in the joint, the gastrocnemius has appeared to me to be slightly contracted, and the case detailed was so; not sufficiently, excepting in the case mentioned, to warrant a division of the tendon, but sufficiently so to prevent the full amount of flexion. Should you find it contracted sufficiently to prevent the foot being fixed beyond a right angle, I would advise division of the tendon; but in adult cases not until after the adduction of the foot is accomplished.

ON THE
TRANSFORMATION OF PUS CELLS
INTO A MUCOUS OR FIBROUS
TISSUE.

BY WILLIAM ADDISON, F.L.S.

[Vide page 727 of last vol.]

I. *Normal Nutrition.*

THE experiments related in the former parts of this memoir were chiefly designed for the purpose of bringing the facts upon which my views of the mode in which the colourless cells of the blood administer to the formation of the tissues and the secretions, are based, out of the domain of the microscope, and of placing them as far as possible within the reach of all who feel an interest in their truth.

I have long been in the habit of comparing what I see through an object-glass of high power, with what I can see by the naked eye, or through a common, or a Coddington, lens, and I find that habit improves the perception wonderfully: thus, the fibrous tissue of the saliva (Exp. 7, ante; vide p. 691 of the last volume of the GAZETTE) may be readily seen by the naked eye, and in a proper light, glistening like tendon; it is admirably shewn with a Coddington lens; the epithelial scales, and the saliva cells, are readily seen lying among the fibres. The colourless cells of the buffy coat of the blood are readily distinguished, and were first seen by me through a Coddington lens: the fibrillation of the fibrine may also be seen through this simple magnifier; and so, indeed, may the dissolution of pus-cells in liquor potassæ, and several other of the facts I have related; lastly, the adhesion of the colourless cells to the tissue in the web of the frog's foot requires only a magnifying power of 150 diameters linear; hence, therefore, those persons who do not possess a microscope, or who possess one of only moderate pretensions, have it in their power to form a judgment on the question, whether or not I have been confounding facts with inferences, or visible things with speculations.

EXP. 10.—One-third of a cupful of muco-purulent expectoration from a patient in consumption, thick, white, opaque, and very stringy or elastic, was mingled with half its bulk of

liquor potassæ; the two were well stirred and beaten together; they formed a transparent, greenish-looking, plastic material, the whole of which was suspended on the blade of a pen-knife. This plastic material, mucus, or fibrous tissue, had the same visible character and mechanical properties as that resulting from the mixture of potass with pus from an abscess in the thigh; and the experiments before related were repeated with it. There were, however, some slight differences: for example, the plastic material in this case having been allowed to remain in the cup for three days, was found at the end of that period to have undergone a separation into an opaque, jelly-like, trembling, and fibrous clot, and a yellowish limpid fluid, having experienced a change analogous to that by which the serum separates from a coagulum of blood*. The clot was of a yellowish-brown colour, and although more easily torn than the plastic mucus from which it came, yet it still presented evident marks of a fibrous structure. The clot was now broken up, and the fragments were thrown into a jar of clear pump water; in four or five hours all colour had departed from them; they had swelled a little, and become of a pure and beautiful ivory white, semi-translucent at the edges. A portion of this white matter, resembling blanc-mange, was taken from the water and placed in strong acetic acid; it soon became whiter, harder, and more friable (No. 1). Another portion, immersed in liquor potassæ, soon became more transparent, more elastic, and mucus-like (No. 2). On adding a little water to No. 1, and applying heat, the fragments of white matter shrivelled up, became hard, tubercle-like, and very friable: they were not dissolved (No. 3). On adding a little water to No. 2, and applying heat, the fragments of white matter were redissolved into a transparent, elastic, white-of-egg-like matter (No. 4). On adding acetic acid to the white-of-egg-like matter, No. 4, it became fibrous, white, and opaque, forming at first a delicate membranous expansion, which, on briskly stirring the fluid, was broken up into white flakes or clots. These results appear to me to shew that the mucus or plastic matter expectorated from the

* Vide MEDICAL GAZETTE, Vol. i. 1840-41, p. 471.

mucous passages connected with the mouth is identical with that resulting from the rupture of pus-cells taken from an abscess in the thigh, excepting only those differences before noticed, and which might be anticipated, between a mucus formed in the living body, and one formed by artificially rupturing pus cells; and they corroborate the conclusion, that colourless blood cells, mucus-cells, and pus-cells, are different forms of the same elementary particles of nutrition.

It appears to me, then, to be demonstrable from my experiments, that the colourless elements or cells of the blood spontaneously transform themselves into an elastic fibrous tissue after their separation from the living structure; or into a plastic transparent mucus (another form of fibrous tissue) when treated with liquor potassæ.

It appears to me also to be demonstrable from my experiments, that a similar fibrous tissue is formed by the disintegration of pus-cells, and by treating the saliva with acetic acid.

The fibrous tissues from these sources appear to have mechanical properties, a physical character and texture, a microscopical or visible appearance, and a chemical composition, so closely allied to the fibrous tissues and membranes formed by the process of nutrition in the living structure, as to leave no reasonable ground for doubting that the latter result from the transformation or disintegration of cells.

If so, then it appears to me to follow as an inevitable conclusion, that there is no such thing in the living organism as a membrane secreting mucus (taking the ordinary meaning attached to the word secreting;) no such thing as an expanse of fibrous, or of any other tissue, so changing the nature or character of fluids, as they filter or transude through its fabric, that the fluid of the blood on one side becomes mucous by merely passing through it to the other; on the contrary, it appears to me that we can no longer hesitate to admit, that mucus, whether conformable to the type of a normal nutrition, or departing from it so as to constitute an abnormal or diseased element, can exist only in virtue of the life of cells. Are these cells generated in the tissue, or are they ulterior forms of blood-cells?

All the facts which I have witnessed support the conclusion that the cells from which mucus originates, are (or have been) blood-cells; the following being their normal sequence, or order of progression.

1st. *Isolated or free*.—Swimming in a limpid fluid; in motion through the vessels and capillary channels of the structure.

(*Blood, or blood-cells.*)

2d. *Stationary*.—United by a plastic element, or fibrous tissue, which they themselves produce.

(*Capillary walls and parenchyma secreting mucus.*)

3d. *Disintegrating*.—Separating and giving place to a fresh succession

(*Mucus and epithelial scales*)

If these conclusions be true with respect to mucus, then I believe them true also of all other secretions; and the sequential order above stated is therefore only another mode of stating my theory of nutrition, another way of viewing the subject. "In normal nutrition, the colourless blood-corpuscles adhere to the tissue forming the boundary of the blood channels; they pass into, and contribute to form, the tissue (the parietes of the capillaries), and are afterwards evolved or thrown off from the nearest free surface—a follicle, crypt, or duct—the epithelial scales and the mucus, or the secretions flowing from the follicles or ducts, being the result of the dissolution of the cells and tissues*.

Now if the sequential order, if the theory of nutrition here stated, be true, then it follows necessarily, upon reversing the series of events, that mucus and the other secretions, before their final transformation, must have been capillary walls, and the capillary walls must have been blood-cells.

What are the facts supporting this conclusion? 1st. An increased amount of the colourless blood-cells in all red or inflamed tissues, where an increased nutrition or secretion is going on: 2d, the identity of these blood-cells with the mucous and pus-cells, which are common to all parts of the structure: 3d, the phenomena displayed in the capillary blood-channels of the frog's foot.

4th.—The experiments related in the preceding parts of this investiga-

* Experimental Researches, 2d Series.

tion—and whether we interpret the phenomena of nutrition from the blood to the secretions, or from the secretions to the blood, we arrive at the same result—that the secretions, the organs of secretion, and the blood, are three marked and recognised stages of cell-transformation. Why cells in one portion of the organism should become bile, in another saliva, and in a third milk, can only be answered by answering the questions, why cells in one portion of a flower are green, in another red, and in a third blue; or why cells in one portion of a fruit—a peach, for example—form the kernel and prussic acid, in another the stone and gallic acid, and in a third the fleshy pulp and sugar.

Lastly, From the active motions visible in the interior of the cells of the blood, of mucus, and of pus, it appears that every molecule essential to a living function has a vital power superadded to its material form; that it is alone, and capable of independent movements; every molecule being alive, it follows that every cell containing them is a living object, and every cell being alive, every organ is alive; and if every organ, then the whole organism: wherefore the conclusion, that the vital power of the body is an aggregate power, susceptible of increase and diminution, and entirely distinct from the person from whom issueth the will*.

II. *Abnormal Nutrition.—Tubercles.*

Exp. 11.—Opaque and cream-like pus was taken from a chronic abscess; some portions were mingled with a few drops of liquor potassæ, and other portions were mingled with equal, double, or treble quantities of water, and then mixed with variable amounts of liquor potassæ. The plastic material, or mucus resulting, was in some instances perfectly transparent; in others, opaque in variable degrees, according to the varying proportions of pus, water, and liquor potassæ. The plastic matter could, with a little care, be spread out into transparent films of any degree of thinness, but it was so extraordinarily elastic that when left to itself it contracted again into a lump.

A piece of glass, four inches square, was procured, and the plastic material spread upon it with the edge of a card;

the glass was afterwards laid in a dilute acetic acid; the plastic matter then became white and opaque, and its elasticity was in a great degree destroyed. After this operation, it was scraped off the glass into water. In this manner, membranes, some of the utmost degree of thinness and transparency, others of a thick, leathery consistence, were formed. The plastic matter, on being submitted to the acid in lumps of various sizes, was changed into an opaque, white, friable substance, resembling tubercle—as, indeed, were the membranes, after a few hours' immersion either in the weak acid or in water.

Exp. 12.—Ten drops of pus, weighing 8 grains, and ten drops of water, weighing 6 grains, were well mingled together, and then three drops of liquor potassæ, weighing $2\frac{1}{2}$ grains, added. The plastic mucus resulting weighed $16\frac{1}{2}$ grains; it was readily suspended on the point of a needle. On immersing it in strong acetic acid, it became opaque, white, and tubercle-like; in a few minutes it was taken from the acid, washed in water, and rolled upon blotting-paper until it ceased to wet the paper. It now weighed 8 grains, the weight of the pus used. But moisture still continued slowly oozing from it, like serum from a clot of blood, and at the end of half an hour it weighed only 6 grains, at the end of an hour 5 grains, and at the expiration of four hours it weighed 4 grains, and could be handled without sticking to the fingers. It had all the microscopical characters of a tubercle.

Exp. 13.—Opaque and cream-like pus, a very short time after withdrawal, was mingled with equal and double quantities of blood-serum, and then treated with small proportions of liquor potassæ. The same kind of plastic material, or transparent mucus, resulted as when water was used, and the same kinds of membrane and opaque tubercle-like matter were produced by the action of the acid.

Exp. 14.—Ten drops of pus weighing eight grains were mingled with ten drops of blood-serum weighing eight and a half grains, and then the mixture was treated with three drops of liquor potassæ weighing two grains. The transparent plastic material resulting was suspended on the point of a needle. It was placed in strong acetic acid, and

* Vide 2d Series of Researches, Sect. III.

secretions appear to me to be colourless blood-cells in some or other of their stages of transformation, and beyond the colourless cell of the blood, which has active molecules within it, I believe no cell to be formed otherwise than perhaps by the passing of two cells into one, or the division of one cell into two, an event which may occur during their structural transformations. I certainly have never seen the slightest disposition to the formation of cells, in any blood-plasma, lymph, blastema, exudation, organizable fluid, effusion, or liquor sanguinis, that I have examined. On the other hand I have repeatedly seen blood-cells, pus-cells, mucus-cells, and cells in lymph, rupture, discharge myriads of active molecules, and thus form a mucous or fibrous tissue, leaving their integument in the form of an altered cell upon the field of the microscope.*

The question what are the stages or the forms of matter between the food and the blood-cells, is not now the subject of discussion. If we take the colourless-cell circulating in the blood as the point of departure, then two distinct lines of investigation lie open before us; the one, leading from this cell back to the food; the other, conducting us from it to the secretions. The former must include the law of nutrition from the food to the blood-cells; the latter the law of nutrition from the blood-cells to the secretions.

It is to the last of these laws, or rather to the latter portion of the general law of nutrition, that my researches have been chiefly directed, and this portion it appears to me may be thus shortly expressed.

Colourless-cells, isolated, free, and in motion in a fluid, become stationary and linked together by a plastic element and fibres; these grow, reach a free surface, discharge their contents, and are eliminated.

In the preceding synoptical table I have attempted to embody my theory of nutrition, and to exhibit the relation between the healthy transformable blood-cells and tissue and mucus; and between the unhealthy untransformable or degraded pus-cells and tubercles.

Your obedient servant,

WILLIAM ADDISON.

Great Malvern, October 9, 1814.

OBSERVATIONS ON SYPHILIS;

TREATMENT OF THE PRIMARY SORE.

By THOMAS BARTLETT, Esq.

Assistant Surgeon, 41th Reg.

(For the London Medical Gazette.)

PRIOR to the publication of John Hunter's treatise, there does not appear to have been any correct idea of the laws which regulate the Venereal Disease, and in consequence, no just views of its treatment. Thus, all modern knowledge of this disease has for its basis, the facts which Hunter collected, and his reasoning upon them. But, if the older writers did not sufficiently generalize, doubtless owing to their minds shrinking from so great a task as the attempt to bring under the action of one general law the discordant materials—as much fallacy as truth—which then constituted the knowledge of this disease; it must, on the other hand, be admitted that Hunter erred in the opposite extreme. And the first wrong direction which his powerful mind took in the consideration of this subject, appears to have been his having believed it almost impossible for the first chancre of a contagion to be cured without its affecting the constitution. This opinion we gather from the following passage in the 7th Section, Chapter 3d of the 5th Part. "In every case of a chancre, let it be ever so slight, mercury should be given internally; even in those cases where they were destroyed on their first appearance. It should in all cases be given the whole time of the cure, and continued for some time after the chancres are healed; for as there are perhaps few chancres without absorption of the matter, it becomes absolutely necessary to give mercury to act internally, in order to hinder the venereal disposition from forming." It is the more worthy of remark, his not having had any doubt of the soundness of this doctrine, as we find this sentence in the same section. "In the cure of chancres I have sometimes seen, when the original chancre has been doing well, and probably nearly cured, that new ones have broken out upon the prepuce, near to the first, and have put on all the appearance of a chancre, but such I have always treated as not venereal." There can scarcely be any difference of

* Vide Provincial Med. and Surg. Journal, June 5, 1811.

opinion now as to the new chancres having had not only the appearance but every other property of the original.

As Hunter allows that mercury does not prevent the origin of fresh venereal infection, it appears strange that he did not see the possibility of his new chancres being venereal. His words are, "Mercury, prior to the action, will not remove the disposition, and of course will not hinder the action coming on afterwards." We can scarcely doubt that in his extended practice some of these new chancres were not healed until after the effects of the mercury in the system had gone off, as Hunter must always have given mercury at the very commencement of the primary sore, as he believed that absorption takes place early in the disease, and as in many cases the mercury must have delayed the cure. From this we may learn that no powers of mind can obviate the necessity of each circumstance that goes to make up a link in the chain of thought in the inductive philosophy, being thoroughly substantiated, before it is admitted as a fact. By how many years has our knowledge of the venereal disease been retarded by this unfortunate oversight of John Hunter? And how many miserable people would have saved their noses and their palates which have been lost to them by the general belief in the truth of his theory?

Is not the infrequency of secondary symptoms when the primary sore is quickly healed owing to absorption not taking place at its early stages? Is it not, therefore, requisite that a primary sore should have existed some time before the lues venerea of John Hunter can arise, unless where there is some great peculiarity of constitution? And does it not follow that the greater prevalence of the secondary symptoms when mercury has been given for the cure of the primary sore, and immediately on its appearance, is owing to its exhibition before absorption has taken place, and while the disease is purely local? So that the venereal virus is absorbed into the constitution, when all danger of such a contingency is forgotten, owing to a premature salivation. Assuming, then, the prudence of giving mercury for local venereal affections, would it not be more judicious to delay its exhibition until the primary sores have healed, as we may be certain that no absorption can

then take place, by which treatment it would be impossible for the secondary symptoms to arise; unless, indeed, the healing of the primary sores had been neglected?

Since Hunter's time, the army surgeons, under the guidance and direction of Sir James McGrigor, the Director General, have not been slow to turn to account, in the investigation of this disease, the great field of knowledge which their profession afforded them. And, as their views did not coincide with those generally entertained, it was fortunate that the result of their experience was given to the world under the sanction of the head of their department, as his name could not fail to carry such weight with it in matter of science as to cause a doubt in the minds of all as to the correctness of their opinions. But even with this advantage, the treatment of syphilis adopted in the army has not become so general as might have been anticipated, owing in a great measure to the respect entertained for all the axioms of John Hunter, and also, in no small degree, to the circumstance of civil practitioners not being able to trace the medical history of the patients after the immediate treatment is concluded. From this it follows that surgeons in civil life cannot fully appreciate the accuracy of Army Medical Reports resulting from the admirable system of placing on record, at the period of its occurrence, every fact in the medical history of each soldier, which has been brought to perfection by Sir James McGrigor. With reference to the practical point, it may suffice to mention, that as the chief indication in the Hunterian treatment of primary syphilitic sores is to secure the system against the effects of the absorption of the venereal virus, so the army treatment of these sores, in the present day, is to skin them over as quickly as possible, without mercurialising the system.

In the non-mercurial treatment of chancres, it is highly important to ascertain the readiest means of healing them, as the chances of absorption are increased in an exact ratio to their duration. On a careful consideration of this point, it occurred to me that as blackwash was a good application, its active ingredient would probably cause them to heal quickly; and having the good fortune at this time to have a large field of observation, owing to my

being in medical charge of the 51st Light Infantry, in consequence of the absence on leave of Surgeon Miller, I put it into practice, and have never departed from it since. The manner in which I used it was the following. I applied a dry stick of lunar caustic lightly over the whole surface of the chancre, and then dry lint; on the falling off of the slough, which sometimes takes place in 24 hours, but more generally in 48, dry calomel was carefully sprinkled over every part of the sore previously well washed; after which a strip of lint sufficiently long to surround the penis was applied after it had been wetted with cold water. The further treatment consisted in applying calomel and wet lint once a day in this way, after the sore had been thoroughly cleansed from all the discharge by luke-warm water. When there is a short prepuce, strips of sticking plaister are required to approximate its extremities to prevent the lint falling off. Whenever the chancre affects any portion of the frænum, division by the knife is necessary to prevent the cure being retarded. No constitutional treatment is necessary. Some cases treated in this way are mentioned in the *Lancet* of the 30th June, 1838, by Mr. Burton, of the African Corps. The medical registers of the 51st Regiment, which were forwarded to Fort Pitt in obedience to the orders of the Director-General on the embarkation of the regiment for colonial service, contain, as far as my knowledge goes, the first recorded cases of this treatment of chancre. When the chancres have been of short duration, and have not the characteristics of the true Hunterian, the application of caustic is not needed, whereby the cure is accelerated, the time being saved of the destruction and the healing up of that portion of substance which the lunar caustic affects. Is it because the venereal virus has not penetrated beyond the external surface of the sore, that it is cured at the commencement without destroying vitality? I have now adopted this plan of treatment in such a considerable number of cases, that I have no hesitation in recommending it to the attention of the profession as the quickest method of healing chancres.

Of the many cases which I have treated in this way, all healed with great rapidity, with the exception of

two. One was the case of a private soldier, in whom sloughing of the cellular membrane of the prepuce came on, when this treatment was discontinued, and warm fomentations and poultices substituted for a time, after which the former method was adopted, and the sore healed kindly, the cure having been delayed about a week. This man was of a weakly habit, and had a very sickly appearance—he was only temporarily under my care. The second case was that of an officer who had neglected to follow the directions given to him, and had reported to me the chancre as cured, while a sinus was running down his penis, which continued for some time, until accidentally discovered, when the treatment was begun *de novo*; greater attention was enforced, and the sore healed quickly, considering its depth, but not before secondary symptoms had come on in the shape of squamous eruptions, pains in shins, and ulcers in the tonsils, which disappeared on affecting the gums with mercury; a gentle salivation being kept up so long as any eruption remained, and the application of sulphate of copper to the throat. This is remarkable, as the only case of secondary symptoms which I have had in my practice since I have adopted this method of cure, when the patient had not had other treatment previously. In this case my patient was not quartered in the same barrack with me, and the regiment received the route during the treatment, which prevented me paying the requisite attention for some time.

Nothing, perhaps, can more clearly show the great improvement which has taken place in the treatment of syphilis since John Hunter's time, than his stating* that it is easier to cure a gonorrhœa than a chancre. This may teach us that with a careful observation of the animal economy, it is possible to set bounds to the advances which may be made in the treatment of disease. But no ground can be gained unless men think for themselves, for servilely to copy the letter of the directions of a great authority, and thereby to close up our observation of what nature unfolds to us, is not a mere submission of our judgment to the possessor of great faculties, but an absolute surrender of our reason. And medicine, least of all

* Section 3d, Chap. 1st, Part 2d, of Treatise on the Venereal Disease.

the sciences, can afford its students an indolent imitation of however great a master, as it is purely a science of observation, increasing its utility by the diligence with which its followers observe the operations of nature, and study their phenomena.

ON THE FUNCTIONS OF THE BILE*.

BY GEORGE KEMP, M.D. Cantab.

Fellow of the Cambridge Philosophical Society.

(*For the Medical Gazette.*)

THE almost universal presence of the bile, or a fluid analogous to the bile, throughout the animal kingdom, and the serious disturbance occasioned by its suppression or abnormal secretion, evidently point it out as a subject meriting the most minute and diligent research. Nor can we overlook the circumstance, that a large portion of the information which we at present possess with reference to its nature and uses, must be considered rather as ingenious speculation than as facts elicited by actual experiment.

That the fluid is not merely, or even to a great extent, excrementitious, that it is not merely an exuvial portion of the blood, is sufficiently proved by the experiments of Berzelius, from which it appears that human faeces contain much too small a quantity of a substance resembling the bile to warrant the idea that it is thus evacuated. The subsequent experiments of Will may also be adduced as confirming this statement, as neither horse nor cow-dung afforded more than $\frac{1}{20}$ th part of a substance soluble in alcohol; and even that small portion, according to Professor Liebig, bears no resemblance, either physically or chemically, to the biliary secretion.

Taking the more probable view, viz. that this fluid is recrementitious, that it is destined either to effect certain chemical or mechanical changes in the contents of the duodenum; thus, according to the opinion of Tiedemann and Gmelin, placing the chyme in a condition more favourable to absorption, and being, at the same time, itself absorbed; still, from the nature of the chyle, as found in the thoracic duct,

the problem remains to be solved, in what state the bile, or the elements of the bile, again enter the system. That the organic elements of the bile, if reabsorbed by the lacteals, assume a different molecular arrangement than they possess in the gall-bladder is evident from the total absence, in the lacteal vessels and thoracic duct, of the characteristic bitter taste of the bile; a physical character so striking that a single grain of dried ox-bile diffused through a pint of water is readily distinguished.

In the following remarks it is assumed, that the chyle bears a certain relation to the food, and that a comparison of the composition of the ingesta with that of the chyle will point out in a general manner the nature of the changes effected by the process of digestion. It is further assumed, that any changes which admit of explanation by supposing them to result from the operation of common and well-established actions, may be legitimately referred to such as their most probable cause: thus, if one body differs from another body in containing one or more equivalents of oxygen, and the former body has been exposed to oxydising agents, it appears in the highest degree probable that oxydation has actually been effected by those agents. Again, if one body differs from another in the quantity of the elements of water which it contains, it is presumed that the one is convertible into the other under favourable conditions.

With reference, then, to the composition of the food, it has now been sufficiently established that in gramivorous and carnivorous animals it essentially comprises two portions, the one adapted to the formation of the nitrogenised, the other for the formation of the non-nitrogenised portions of the animal frame. Albumen and starch may in fact be taken as the types of each respectively.

With reference to the composition of the chyle, it was found, by the researches of Marcet and Macaire, to consist of a body which may be expressed by the empirical formula $C_{5.8}H_{13}N_5O_{21}$; and this must, therefore, represent the sum of the albumen and starch, having undergone the changes necessary for assimilation. Modern researches have proved that the albu-

* Read before the Medical Section of the British Association, Sept. 30th, 1844.

men undergoes but a very slight change in order to render it fit for absorption. Deducting, therefore, the formula of proteine or albumen (for in a certain sense they may be considered identical) from the formula for chyle, the remainder will represent the body into which the non-nitrogenised portion of the food has been changed by digestion; thus— $(C_{58} H_{38} N_5 O_{21}) - (C_{10} H_{31} N_5 O_{12}) = C_{48} H_{7} O_9$.

But the formula for starch is $C_{12} H_{16} O_{10}$; how then may this difference, which has evidently taken place during digestion, be accounted for?

In offering a solution to this question, I would beg it to be distinctly understood that my object is at present merely to direct attention to the remarkable fact, that by the mere action of oxygen on the elements of the bile

The difficulty of instituting a series of experiments sufficiently simple in their condition deprives us of the advantage of a synthetical proof, and at present the subject must remain as an hypothesis, though a very probable one. I hope, however, at the next meeting of the Association, to be able to prove from observation the exact period of digestion at which the bile changes its character. This will obviously be accomplished with ease by passing a ligature over the pylorus of an animal killed during the digestive process, another beyond the ductus communis choledochus, and so on, at short intervals, throughout the length of the duodenum, and by examining the contents of the several segments the point will be ascertained at which the fluid loses its normal characters.

I beg leave, in conclusion, to make a remark on the cause of alkalinity in the bile. From certainly not less than 200 samples of bile of different animals, which I have examined, this fluid has been uniformly neutral when in a healthy state and fresh; a very short time, however, is sufficient to change its character when the mucus of the gall-bladder is present. It will be remembered that this latter body has been proved to be a proteine-compound, all of which undergo decomposition with facility, carbonate of ammonia being at the same time formed; and,

and starch, the result is a body represented by the formula $C_{18} H_{12} O_9$, which is the non-nitrogenised portion of the chyle; and it is highly probable that the action of the pepsin is catalytic, effecting the interchange and combination of the elements of the two former bodies.

Thus the organic portion of ox-bile may be represented by the formula $C_{48} H_{42} NO_{13}$, and by the action of nitric acid on this body we deprive it of the elements of ammonia and obtain $C_{48} H_{39} O_{15}$, which for the convenience of subsequent comparison we shall put into a different form.

in preparing the bile for analysis, great care should be taken to remove the whole of the mucus before evaporation is commenced. The cases in which I have observed it alkaline in the human body were obtained from patients suffering from extreme prostration of the nervous system, particularly those who had died from typhus fever and severe burns.

Some precaution is necessary in testing with turmeric paper, in consequence of the intense colour of the bile; the paper should be carefully washed when removed from the fluid, and even then a line of demarcation will generally be found between the dry and moistened portion; if, however, the mass of the moistened portion retain its yellow colour after being washed, the dark line is manifestly attributed to capillary action.

SUPPLEMENTARY REMARKS.—In addition to the above statement, it will not be considered irrelevant to make a few brief observations relative to the change which the bile undergoes subsequently to its introduction into the gall-bladder, and also to the neutral condition of the fluid when in its normal state.

It is now established by direct experiment* that the hepatic bile

* See my paper in the LONDON MEDICAL GAZETTE, dated Cambridge, May 1st, 1843.

possesses characters, both physical and chemical, differing widely from those of the cystic bile; it is therefore evident that this change is effected by some agent contained in the gall-bladder, and the only bodies to which we can refer this agency is the muens of the gall-bladder or the epithelium of that organ; it is, however, a remarkable fact, that although we should imagine *a priori* that on this account the contents of the gall-bladder would be always various in composition, ultimate analyses, conducted on a very extensive scale, afford results so nearly uniform, as to leave no doubt that the conversion of the hepatic into cystic bile occurs immediately on its introduction to the gall-bladder, or that these fluids are almost identical in their elementary composition, although differing remarkably in their physical characters as well as in their chemical relations to other bodies.

Again, the bile in a healthy and perfectly fresh state is neutral; if, however, when emptied with the muens out of the gall-bladder, it be left in contact with that substance, a very short time is sufficient to bring about an alkaline reaction; and this effect is greatly accelerated by a moderate temperature. Now in the living animal both these conditions are present, and yet, in the case of animals slaughtered after long-continued fasting, where there is invariably a large accumulation of bile, and when the fluid has for many hours been exposed to the joint influence of heat and the mucus, it still retains its normally neutral state in the gall-bladder, then some force must be in operation, counteracting the tendency to molecular change which so speedily manifests itself out of the body. This is an interesting and may be a very important subject of research.

ON SCIENCE AND PRACTICE.

To the Editor of the Medical Gazette.

SIR,

THE position which I advanced in my last communication, viz., that all disease is intermediate between health and death, and the obvious and direct inference which follows upon the reception of this truth, that those who are ill require to be *raised up to health*, instead of being lowered and antiphlo-

gisticated as they are at present, is one of no trifling importance; because it exhibits in a very clear and striking point of view that the endeavour to cure inflammatory diseases by antiphlogistic means consists of efforts which are not exerted in the right direction. If, therefore, this truth be established, and if at the same time it lead to other more speedy and efficacious means of cure, it will work a great revolution in the modern practice of medicine. In saying that persons who are ill require to be raised up to the standard of health without any preliminary lowering, of course I shall be met by a reference to the multitudes of cases recorded as having been treated antiphlogistically with a happy issue. I have no wish whatever to deny these facts, but I do say there is nothing in the circumstance of persons having recovered under such treatment to show that they might not have recovered more speedily under a very different plan: and when it is considered how many die, notwithstanding the most scrupulous employment of the antiphlogistic treatment in all its rigour, and how many of those who do not die are several years in regaining their health, while many, particularly those who are no longer young, only drag on a miserable existence for a few years, and never recover at all, I think the most prejudiced must admit that some improvement is highly desirable. The first instance belonging to this latter class of severe cases where the mischievous tendency of the antiphlogistic treatment is most apparent, which arrested my attention, occurred as much as seventeen or eighteen years ago: it was a case of inflammation of the iris (right eye), the patient a well-grown young man, æt. 19: he was bled, mercurialised, purged, and starved, *secundum artem*. Under this treatment the eye became clear, and remained well for several weeks; occasionally, however, somewhat dull and red towards night. At the end of this time the iris became again inflamed; the same treatment was repeated, and again the eye became clear and the sight good. To be brief, relapse after relapse occurred, the interval of ease between each becoming successively less and less, until at length there was no remission at all. While this was going on, he had been brought to London;

the first authority in such cases was consulted, and he was condemned to a continuation of the same treatment, with the addition of blisters, setons, and issues. More than two years were passed in this manner, and by that time he was reduced as low as it was possible to be—lying in bed, too weak to stand, with fits of convulsions constantly recurring, each of which was expected to be the last, and the eye still inflamed. These convulsions had nothing of the character of epilepsy about them; they consisted in loose and irregular contractions of the voluntary muscles, just such as may be seen at any time in animals which are dying from excessive loss of blood. By dint of great attention, however, he recovered a little, and then the gentleman under whose immediate care he was, seeing how unavailing all previous treatment had been, cautiously commenced an opposite plan, as it could be borne. Under this plan the patient eventually recovered completely, with the exception of the iris being somewhat discoloured, though he did not entirely throw off the effects of what he had gone through until within the last three years. This was the first case of the kind which occurred within my observation, and the latter part of it especially, in which I saw a most obstinate inflammation getting well under a plan of treatment which I had always been taught to believe would be most pernicious, made an impression on my mind which will probably never be effaced. It was a "great fact" which I could neither deny nor understand; it intruded itself into my thoughts day and night, nor did it suffer me to rest until a thorough investigation into the whole subject of inflammation, the result of which appeared in the pages of the *GAZETTE* some ten years ago, revealed the explanation of it. It is remarkable, that although those papers contain the only complete review which has ever been taken of the whole subject of inflammation, for the purpose of showing how modern doctrines are affected by the facts which have been discovered since the death of Mr. Hunter, no one, not even he whose *periscope* eye professes to take cognizance of the "spirit of the periodicals," should have taken any notice of them. It may be, perhaps,

because I have drawn no such picture as that of inflammation sitting like a hen in a part during hatching, the "period of incubation," constituting a picture of such as has elsewhere been presented to us. How much more easy and pleasant it is to allow free play to the imagination, and to speculate upon the attractions and repulsions of molecules and globules, than to be bound and fettered by stubborn facts. In the present state of physio-pathological science it is scarcely possible for practitioners to believe that such cases as the one I have just mentioned, which are now protracted through four, five, or more years, ought to get well in less than as many months, or that any of the harassing circumstances connected with them can be at all owing to the antiphlogistic treatment; a sufficient cause for every relapse is speedily found either in some supposed error in diet, taking fresh cold, in the unusual severity of the disease, in peculiarity of constitution—in any cause, in short, but the true one: the science is never mistrusted; it is never dreamed that the active treatment has had art or part in producing such results. If there be any doubt at all, it is rather whether the bleedings were sufficiently copious in the first instance, so that a surgeon is more likely to blame himself for not having bled enough, than to entertain the least suspicion of having bled too much. A very large proportion of the medical profession consists of individuals who pique themselves on their experience, gained in many long years of practice, and their universal cry is, "give us practical facts; tell us the particular quantities and combinations of medicines, and the occasions which require them:" these gentlemen would rather trust to their memories to supply them with a particular remedy for each particular emergency that may arise, than give their minds to the comprehension of a general principle. Now the value of these practical facts depends entirely on the power of the practitioner to apply the remedies at the moment they occur; hence the great demand for practical works, and the importance which has of late years been attached to accurate diagnosis, in order to be as sure as possible of always employing the remedy under precisely

similar circumstances. Each man, therefore, collects his stock, and prides himself as being superior to his neighbours in proportion as he flatters himself that his tact enables him to employ it at the proper moment. The worst part of these practical facts is, that they are very apt to fail precisely at the time when success is most important; from that moment all confidence is withdrawn from them, and they are regarded simply as things there may be "no harm in trying." It is this state of things which causes the practice of medicine to border closely upon empiricism, and enables the quack, when reproached by the physician, to return the "in quoque" with some show of justice. The one thing needful, to place the practice of medicine in its proper position, is the correction of the science by which it is directed: the effect of this will be to simplify practice and to impart confidence, because if we can understand why a remedy succeeds in one instance, and why it fails in another, we shall be able to establish general principles on sound foundations, and be able, also, to vary and modify it so as to ensure its success in a much wider range of cases than before, even though the circumstances may not be precisely the same in each.

I think the most convenient course to be pursued, in carrying out the endeavour to place the science and the practice of medicine more in unison with each other than they are at present, will be to show what function maintains health, how it may be injured, and how it may be restored. It must be borne in mind that what maintains health and what constitutes health are two very different questions, and may be taken separately. I propose to confine myself to the former; but as this letter has already extended to a considerable length, I shall defer entering upon it until my next communication.—I have the honour to be, sir,

Your obedient servant,

J. W. EARLE.

Cheltenham, Oct. 1844.

P.S. If your correspondent "Gyensis" will take the trouble to read my last letter again, till he is quite sure he understands its meaning, I shall be happy to attend to any observations which he may then be pleased to offer.

ON THE

PATHOLOGY AND TREATMENT OF OVARIAN DISEASES;

WITH CASES.

By DR. SAMUEL J. JEAFFRESON,

Physician to the Chelsea, Brompton, and Belgrave
Dispensary, &c.

[[Continued from p. 46.]

(*For the London Medical Gazette.*)

I SHALL now take the liberty of drawing the reader's attention to the following statistical table of the results of 74 operations for the extraction of ovarian tumors. The materials from which this table has been drawn up have been chiefly derived from the Medical Gazette, Lancet, and Medical Times; they have been also compared with Dr. Churchill's table in the Dublin Medical Journal, from which source three or four cases previously omitted by myself have been copied; and for an account of the three operations by Mr. Lane I am indebted to that gentleman himself, whose readiness to afford me every assistance and information, and desire to promote a strict scrutiny into the result of these operations, did equal credit to the kindness of his heart and the soundness of his judgment.

The table has been divided into three great classes.

1st. Of the cases in which the ovarian tumor has been removed by the large abdominal incision, the hand being introduced within the peritoneal cavity for the purpose of separating adhesions, passing ligatures on the pedicle, &c.

2dly. Of the cases in which a small incision has been made, through which the cyst has been drawn (first emptied of its contents, and tied externally); and,

3dly. Of the cases in which the removal of the tumor has been attempted, but abandoned on account of adhesions, or in which the tumor has been found to be other than ovarian, or in which no tumor has been found at all.

STATISTICAL TABLE
OF THE
RESULTS OF SEVENTY-FOUR OPERATIONS FOR THE EXTRACTION OF OVARIAN TUMORS.

CLASS I.—*Tumors removed by long incision; the hand introduced into the peritoneal cavity.*

No.	Age, &c.	Date.	Name of Operator.	Nature of Incision.	Character of Tumor.	Result.	Remarks.
1	Mrs. Crawford	1817	L'Ammonier	4 inches	Common abscess of ovary?	Successful	Tumor divided previously to removal
2	A Negress		Dr. M'Dowall	9 inches	15 pints fluid; sac $7\frac{1}{2}$ lbs.	Successful	Tumor divided before removal; division followed by severe hemorrhage. It adhered firmly to fundus uteri and bladder
3			Dr. M'Dowall	9 inches	Not described	Successful	
4	Ditto		Dr. M'Dowall	9 inches	"Scirrhus ovarium," 6 lbs.	Successful	
5			Dr. M'Dowall	Long	Not stated	Successful	
6	33	1821	Dr. N. Smith	3 inches	Monolocular?	Successful	I cannot discover that these operations were conducted on the principle first introduced by Mr. Jeaffreson, and therefore presume the hand was introduced within the abdominal cavity
7	30		Dr. A. Smith	3 inches	Monolocular?	Successful	
8			Dr. Quittenbaum	4 inches	Not stated	Successful	Two gallons of ascitic fluid first drawn off by trocar. Had been tapped seven times for the ascites. Firm adhesions round umbilicus for 3 or 4 inches
9	20	14 Sept. 1829	Dr. Rogers, New York	Moderate	Mixed; solid part $3\frac{1}{2}$ lbs., whole about 12 lbs.	Successful	The ovary of the opposite side was found diseased, but too adherent to pelvic viscera to be removed; it was about a quarter the size of the one removed.—She afterwards lived servant with Dr. Blundell
10	36—single		Mr. Lizars	From ensiform cartilage to symphysispubis	Not described; ascites	Successful	Firm adhesions to brim of pelvis, colon, and abdominal walls, partly overcome by dissection, and partly by tension and the handle of the scalpel
11	25—single		Mr. Lizars	Long	7 lbs.	Died 56 hours after operation of gangrene of peritoncum	

12	38—married; family 38	June 1820	Dr. Chrysmer	Long	8 lbs.	Successful	Became pregnant 16 months after operation
13		1820	Dr. Chrysmer	Long	6½ lbs.; mixed.	Died 36 hours after operation	Considerable adhesions; ascites; disease complicated by humped back, deformed pelvis, tuberculated liver, and diseased mesenteric glands
14			Dr. Chrysmer	Long	7½ lbs.; mixed; almost bony hard in parts	Died 30 to 36 hours after operation	Ascites; considerable adhesions; died of peritoneal inflammation
15	31		Dr. Ritten	Long	Fluid; monocular	Successful	Dr. Granville attributes the fatal termination to copious venesection practised by the medical superintendent under the false alarm of peritonitis supervening
16	30 to 40	21 March 1827	Dr. Granville	9 inches	8 lbs.	Died 3 days after operation	Adhesions slight; ascites
17			Dr. Dohlhoff	Long	Mixed	Died	Extensive ascites; numerous and troublesome adhesions. Had been frequently tapped previously for ascites
18	46	Sept. 1842	Dr. Clay	Long	Mixed; multilocular, and chiefly fluid; 17 lbs. 5 oz.	Successful	Considerable adhesions and plentiful ascites
19	57	Sept. 1842	Dr. Clay	Long	Mixed; 9 lbs.	Successful	Attachments of tumor spongy, vascular, and so broad that the ligature could with difficulty be applied so as to prevent hæmorrhage. She died in a state of syncope. She had been previously subject to fainting fits
20	39	Nov. 1842	Dr. Clay	Long	Mixed?	Successful	
21	45		Dr. Clay	Long	Very solid; 13 lbs.	Died 1½ hour after operation	
22	22		Dr. Clay	Long	Mixed	Successful	
23	40		Dr. Clay	Long	Mixed	Died	
24	32	1843	Dr. Clay	Long	Mixed; 29 lbs. 14 oz.; about 14 lbs. solid, 16 lbs. fluid	Successful	
25	59		Dr. Clay	Long	Mixed	Died	
26	46		Dr. Clay	Long	Mixed tumor	Successful	
27			Dr. Stilling	6 inches	Not described	Died	
28			Mr. Morris	Long	Not described	Successful	

29	58	6 Nov. 1842	Mr. Wahe	13 inches	Chiefly fluid, in two or more cysts; solid part, size of double fist, very hard	Successful	No adhesions
30	57	30 May, 1843	Mr. Wahe	12 inches	Chiefly fluid; 17 lbs.	Successful	No adhesions; some hæmorrhage from the divided pedicle, "proving the advantage of the long incision to remove blood-clots, &c." Patient narrowly escaped, and laboured under phlegmasia dolens after operation
31	19 to 20	12 Sept.	Mr. Wahe	14 inches	A single fluid cyst principally; a moderate portion of solid matter, very vascular; weight 28 lbs.	Successful	No adhesions
32	55	19 Oct. 1843	Mr. Wahe	15 inches	14 lbs.; 5 lbs. solid, rest fluid, and some cheesy	Died	Ascites. A large fibrous tumor of uterus complicated the disease; this was not diagnosed during life. The resting of this tumor on the abdominal incision appears to have been the cause of death, by preventing it healing, and giving rise to low inflammation with suppuration, &c.—It is fair to state that the operation was undertaken only at the urgent desire of the patient, and contrary to the judgment of Mr. Wahe and Dr. Blundell
33	35	26 June, 1843	Dr. F. Bird	3½ to 4 inches	20 lbs.; chiefly fluid, a solid portion size of an orange	Successful	Two slight adhesions. Tumor emptied of its contents before removal. Disease of 17 years' duration; had been tapped ten times
34	35	28 Jan. 1844	Dr. F. Bird	Small at first, afterwards extended	Multilocular; 35 lbs.	Successful	Tumor divided previously to removal. Some adhesions anteriorly, which readily gave way
35	21	Nov. 1843	Dr. F. Bird	4½ inches	Chiefly fluid and monolocular; 27 lbs.	Successful	No adhesions. Cyst evacuated before its removal
36	21	1 April, 1844	Dr. F. Bird	4 inches	Fluid; monolocular; 29 lbs.	Successful	

37	32		Mr. B. Cooper	Long	Chiefly solid, with some fluid cysts; 32 lbs.	Died 7th day after operation	Death from peritonitis. Malignant tubercle was also discovered in fundus of uterus; some few adhesions about seat of former trocar wounds
38	29	3 Sept.	Mr. Greenhow, Newcastle	Long	Chiefly solid, with some fluid cysts; 32 lbs.	Died 7th day after operation	Adhesions with omentum separated by bistoury. Peritonitis; some points of inflammation and ulceration about the pyloric orifice of stomach
39	37	20 Oct. 1843	Mr. Southam	9 inches	Solid matter, with several cysts; 4 lbs. 12 oz.	Successful	Ascsites 14 lbs.; no adhesions
40	47		Dr. Hopfer	Long	7½ lbs.; parts very hard, parts containing fetid pus	Died 30 hours after operation	Adhesions.
41	38		Dr. Hopfer	Long	Not described	Successful	Great stress laid upon the value of opium in the symptoms following the operation
42		23 June, 1843	J. L. Atlee, M.D.	9 to 11 inches	Both ovaries—one size of goose's egg, other not stated; "containing hydatids"	Successful	Ascsites to about 39 lbs.; one tumor firmly adherent in pelvis
43	28	1843	Mr. Lane	From umbilicus to pubes	Simple cyst, very thick; 14 pints	Successful	No adhesions. Phlegmasia dolens followed operation. Mr. Lane performed paracentesis ten days previously to the operation, but found great inconvenience from this proceeding; the lower part of the collapsed and emptied cyst had got so completely jammed into the pelvis as to be with difficulty removed, and to give the semblance of strong and general adhesions; this, however, was due in part to atmospheric pressure, and they were readily removed when air was admitted by getting the fingers under the folds of the cyst
44	38	1844	Mr. Lane	From umbilicus to pubes	Fluid; multilocular	Successful	The cyst was sessile on, and firmly attached to, the fundus and neck of uterus. Having emptied the larger cysts, the ligatures were applied round a portion of the collapsed cyst

45	45	1843	Mr. Lane	From umbilicus to pubes	Two tumors, size of the closed fist, and $3\frac{1}{2}$ gallons of fluid	Successful	Extensive adhesions from one hypochondriac region to the other, of a hand's breadth. Their separation illustrated the advantage of Mr. Lane's mode of incision, for the hand forced gently between the abdominal walls and the cyst separated the adhesions. Cyst emptied before removal. The last paracentesis was followed by entire refilling of cyst in five weeks
----	----	------	----------	-------------------------	--	------------	--

CLASS II.—*Small opening, cyst drawn through the opening and tied without introducing the hand into the peritoneal cavity.*

46	37	March 1836	Mr. Jeaffreson	2 inches	Unilocular; fluid	Successful	After treatment, opium and digitalis chiefly The incision was increased to 3 inches, to allow of the escape of a small solid tumor attached to walls of cyst
47		July 1836	Mr. King	3 inches	Unilocular; fluid	Successful	
48	35	Nov. 1837	Mr. West	2 inches	Unilocular; fluid	Successful	Death by enteritis. Other ovary was found to be diseased
49			Mr. Crisp	—	Unilocular; fluid; 3 gall.	Successful	
50			Mr. West	—	Unilocular; fluid; 24 pints	Successful	
51	Miss S., 23 A. D., 21	9 Sept. 1840	Mr. B. Phillips	—	Unilocular; cyst thick; 330 oz. of fluid	Died 5th day after operation	

CLASS III.—*In which the tumors could not be removed from adhesions, proved to be other than ovarian tumors, or in which no tumor was found, &c.*

52	54	31 July 1843	Mr. Waine	5 inches	Chiefly fluid and unilocular	Recovery in statu quo	Removal abandoned on account of adhesions
53	34—single	1826	Dr. Granville	9½ inches	—	Recovery in statu quo	Removal abandoned on account of adhesions
54			Mr. Lizars	Long	Size of full period of utero-gestation, or larger	Recovery in statu quo	Removal of tumor abandoned on account of adhesions. Two punctures and incision into mass followed by some blood only

55	Dr. Dieffenbach	Moderate	—	Recovery in statu quo	Removal abandoned on account of adhesions. Puncture of tumor followed by hemorrhage to a very serious extent
56	Dr. Martini	9 inches	—	Died 36 hours after operation	Removal abandoned on account of adhesions. "1½ pint of serum" followed a puncture; part of the cyst was removed.
57	Widow, 27	5 inches	Size of seventh month of pregnancy	Recovery	Adhesions to pelvis and pelvic viscera
58	Dr. Clay	Long	Apparently solid	Died 6th day after operation	Removal abandoned on account of adhesions posteriorly. A fistulous opening was established through the wound by bringing out a portion of cyst, and kept open discharging up to the 70th day, at which she was discharged
59	Anonymous— Froiep's Notizen	Long	—	Died	Removal abandoned on account of adhesions. Tumor bled when punctured; operation followed by phlegmasia dolens
60	Dr. Dohilhoff	6 inches	—	Died	Tumor could not be removed owing to its broad base and attachments to os innominatum.
61	Mr. West	Small operation	Fluid; monocular?	Recovery in statu quo	Removal abandoned on account of adhesions
62	Mr. West	Small operation	Fluid; monocular?	Died	Removal abandoned on account of adhesions 11 gallons 8 pints of fluid withdrawn. The patient's constitution was previously much shattered
63	Mr. Hargreaves	Small operation	Mixed form?	Recovery in statu quo	Removal abandoned on account of adhesions
64	Guy's Hospital 1839	Small operation?	Two cysts	Died	Removal abandoned on account of adhesions
65	Dr. M'Dowall	Long	—	Recovery in statu quo	Removal abandoned on account of extensive adhesions to uterus and bladder
66	Dr. Dohilhoff	5 inches	No tumor!	Recovery	
67	Mr. King	Small operation	No tumor!	Recovery	

Mr. Lizars	Long	No tumor!	Recovery	The best opinions of Edinburgh confirmed Mr. L. in the existence of ovarian tumor : The operation undertaken at the urgent desire of patient. She had previously had lumbar abscess. She had been twice tapped ; but with what result is not stated
Dr. Clay	Long	Uterine tumor	Died	Complicated with ascites. The tumor, which was supposed to be ovarian, and the cause of the ascites, turned out to be a mass of intestines glued together by adhesions
Dr. Clay	Long	Hydatid tumor	Recovered	
Dr. Clay	Long	Pelvic tumor	Died	
Dr. Clay	Long	Uterine tumor	Died	
Mr. Heath	—	Uterine tumor	Recovery	
Dr. McDowall	Long	Intestinal tumor	Died	
68				
69				
70				
71				
72				
73				
74				

Thus it would appear from the foregoing table, that the removal of ovarian tumors has been attempted in 74 cases, with the following results :—

In 37 cases the tumor was removed, and the patients recovered.

In 24 cases the operation was followed by the death of the patient : of these 24 fatal cases, the tumor was removed in 14, could not be removed on account of adhesions in 6, and was found to be other than ovarian tumor in 4 cases.

Thus, again, in 74 cases in which the operation for extraction of ovarian tumor has been undertaken, it has been completed in 51 instances, in 14 out of which 51 instances it has been followed by death, and in 37 by the successful removal of the tumor and the recovery of the patient ; whilst out of the 74 cases selected, it was found impossible to carry out the intentions of the operator in 23 ; or, in other words, the diagnosis was not sufficiently accurate to enable the surgeon to foresee the impracticability of carrying out his intentions. Of these 23 cases, 13 recovered with life, to remain *in statu quo* ; 10 died. The cause of failure was impossibility of removing the tumor on account of adhesions in 14 cases ; no tumor was found in 3 cases ; and the tumor proved to be other than ovarian in 6 instances.

[To be continued.]

ACESIUS :

A SURVEY OF THE ETHICAL BEARINGS OF
MEDICINE.

By C. F. H. MARX, M.D. &c.

(For the London Medical Gazette.)

[Continued from p. 16.]

TO JOHN NOEL HALLE,—

YOUR life presents us with a picture of all that the sensitive practitioner is called upon to endure ; you will surely, therefore, allow me to address a few words to you, and to open my heart upon the *disagreeables* in our profession.—No one can possibly understand me better.

That you had to bear the torture of stone in addition to your other sufferings, for some time before your death in the year 1822, at the age of 68, was a sore addition to an existence already sorely tried, and one which nothing

but the strength of resignation you possessed enabled you to endure with your wonted meekness.

The degree in which you proved yourself the protector, the friend, and the stay of the poor, was amply shewn in those eventful times, when so many of them paid to violence the debt due to nature. You felt in all its bitterness what he feels who throws himself with his whole soul into the service of others, and yet is misunderstood; and again, you shewed how the grandeur of innocence could force respect even from madness.—The fierce dog suddenly let loose upon his benefactor, often knows him only in the moment of attack, and instead of tearing, fawns upon him, and licks his hand. In the tempest of all the passions let loose, you preserved mental serenity both for yourself and others. To you it was permitted to visit Malesherbes in prison, and to receive his last farewell; and you, too, were the author of the petition for Lavoisier.—Could the stones of Paris speak, they would say you had lived but to wipe away tears.

Every proposition in medicine having the well-being of the community for its object, could reckon upon you as its advocate and promoter: how unwearied were you in your efforts to spread the blessings of vaccination!

For personal sacrifices and thanks received, you kept no record in the way of debtor and creditor account; had you done so, it would not have been difficult to have guessed on which side the balance must have lain.

You ever acted with sympathetic heart; you were impelled to do so by your intimate constitution, and could do no otherwise. You never expressed surprise when gratitude failed; you much rather did so when it was expressed.

Franklin relates, that having lent a sum of money to a certain individual, he requested his debtor, when he came to pay him back, that he would lend it to another in want of assistance, on the same terms, and that he, in his turn, should do the same; and so on for ever. Even so did you regard the ability to do good as a trust committed to your care—as a debt that was still to discharge.

But is it not true, when the physician is labouring even in the spirit that Fouclon taught—in the spirit, indeed,

in which MAN ought ever to be found labouring—that the burthen of his office, or rather the large infusion of selfishness he encounters, weighs oft like lead upon the heart?

The load of grief which the physician, as opposed to his profession and pretensions, carries with him from the house of death, is indeed far greater than can be imagined by those whose thoughts and converse are but of business and handicrafts.

There are physicians, it is true, who seem to make it an affair not as between themselves and the patient, but as between themselves and the disease; who have to do, not with a dying man, but with death; who proceed *secundum artem*, and content themselves with common places of morals,—but I would not remind you of these. And yet, how should the great event of death excite deep sympathy, when the cessation of suffering meets us as a blessing? And death, too, often deals with the sick man as the gardener does with the tree he would transplant, when he gradually digs round it, and cuts off its outer roots. The departure from the sphere of customary relations then takes place, so far prepared, that when at length it comes to pass, it is considered but as a natural consequence of incidents that have gone before.

But what is the state of affairs when a great calamity falls like a thunderbolt upon a house, wholly unexpected, and where the physician, it is presumed, alone can save? where life does not cease gradually and smoothly, as the leaf first fades, and then grows sere, and finally falls from the tree,—or as a clock runs down; but where nature, like the tragedian, compresses all that is most fateful and moving into one, and that the last scene? The physician comes home exhausted, and flatters himself that he will now forget the labours of the day, and gather fresh strength for to-morrow's toils in sleep; he has scarcely laid him down, when he is summoned to an infant in extremity from croup. The parents meet him as an angel sent from heaven for their deliverance; it is the first time in the course of the day that they have had a thought for a human being beyond their only child; they hang upon his looks with fear and trembling; they seek to interpret every

motion, every question, every order, into hope for their infant; the mother smiles him thanks, half in despair, because the child is quiet; the father, moved, seizes his hand. The lull is of short duration: the infant cannot any longer cough; it throws the head back, and struggles convulsively with outstretched hands for breath,—in vain; it is gone!

What now bears the physician company from the door, but the cry of despair and anguish of the crushed parents!

Should the practitioner himself, on the back of such an affair as this, happen to lose a friend,—one to whom, perchance, he had dedicated himself in thought and deed for years,—where is *he* to look for sympathy? The world treats him as though he needed none: in the blighted spot of his affections, the memory of the sharer of his cares and anxieties, far more than of his joys, alone takes root and grows. On him, exhausted in body and distressed in mind through his vain efforts to save, no one seems to waste a thought.

Another is pacing his chamber, passing in review the events of the day, and having the morrow in dim perspective before him,—he is summoned in breathless haste to a woman flooding to death perchance, in circumstances where decision and promptness may or may not avail to save; or where a perilous operation, involving the life of the mother or the child, perhaps of both the mother and the child, is imperative.

And it is not enough that, in such momentous circumstances, he must needs, like the boy at the lottery wheel, draw forth either blank or prize—like the gallows' priest, speak words of consolation into senseless ears—like the swimmer, who risks his life to save another's, and only reaches the shore with a rescued corpse;—no, he must still undergo the ordeal of perverse and incompetent criticism; and, in running the gauntlet betwixt suspicion and malice, all he has for it, is often to use his conscience, void of offence, as the soldier under the lash does a leaden bullet—bite upon it, that he may not scream for agony!

For the dead there is an euthanasia; for the sorrowing survivors visits of condolence,—who troubles himself

about the sorrow-laden physician? And yet, has not he the most frequent opportunity of knowing that in separations, tears are the true aqua regia, or assay-water of the soul, and that a syncope is the best tranquillizer of the blood?

But I hear you exclaim:—"O desine renovare dolores!" and I will even cease from complaining. I will rather yield to the hope that, in the matter of sparing the physician's feelings, improvement may yet dawn, as it has already broken upon most things else.

Whoever has read the letters of Zimmerman, which only appeared after his death, will remember how he says that in the houses of the great there is a seat indeed for the medical man, but that it is without arms or a back: and that the court and body-physician may drive a well-bred horse, but not with leathern harness*.

The word in most constant use in Japan is *PATIENCE*! Golownin's account of his travels in that country, and of his imprisonment there, contains much that is moving and interesting to the European medical practitioner.—You, Hallé, practised patience, and exercised forgiveness to such an extent upon earth, that you have surely had the palm of victory put into your hand in heaven!

ANALYSES AND NOTICES OF BOOKS.

"L'auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALEMBERT.

The Principles of Surgery. By JAMES MILLER, F.R.S.E., Professor of Surgery in the University of Edinburgh, &c. &c. Pp. 716. Edinburgh: A. and C. Black.

We have long given up the hope of seeing the literary market supplied with those books only that are really wanted in it. Professional men in the present day are very much in the position of dealers in some perishable commodity, of which there is a glut, yet which must be got rid of before night-fall, which must be sold at any price, however low. There is such a host of them, physicians, surgeons, surgeon-

* As in Russia, at the present day, no one is allowed to wear ermine who is not of the imperial family, so, in former times, the court in France and Germany alone used leathern harness; the commonalty drove with ropes.

apothecaries, apothecaries, dentists, druggists, &c. &c. each jostling the other, and striving to attract the notice of the public—to say nothing of the shortness of an actual professional life, which scarcely commences before 30, and ends under the most favourable circumstances about 60—that no man can afford to hide the light that is within him, and wait for the practice that waiting patiently for will not always bring; no, he must make such capacity as he has to illuminate available. Like the public-spirited individuals in the metropolis, who, in foggy weather, expend part, perhaps all, of their substance in links, which they generously burn for the behoof of passengers over dangerous ground, always in expectation of receiving half-pence in return, he must proclaim himself to the world; and the sole and only legitimate means—for we differ from those who say it is not legitimate—that lie open to the professional man of doing this, are the pen and the press. Books, in truth, are seldom written nowadays because their authors have anything to communicate that is not perfectly well known to all the world; it is either because a man is a professor that he now writes a book,—and this he may do advantageously with reference to his pupils; or it is, because he conceives that he has worked out and obtained a clear and comprehensive view of the whole of a particular subject, that he takes up the pen; and, able to use his tool, it is unquestionable that he may do good service with it in this way. Finally, and we fear that this is by far the most frequent case, he feels the necessity of making his whereabouts known to the world; and as it is not yet the custom for what are called regular surgeons and physicians to advertise themselves openly as such, and to announce by the bellman that they may be consulted daily at No. so and so, in such and such a street, there is nothing for them but to fly to the ink-bottle. The false delicacy just alluded to, we may hope in time to see redressed, or got over; for we already notice people who think themselves very regular—Doctors and Presidents and Professors, F.R.S.'s and F.R.S.C.E.'s, paraded in the advertising columns of *Punch*, and the *Dispatch*, and the *Satirist*, in company with Messrs. Goss and Perry, Cockle

and Parr, and Hodgson and Abbot's "pale ale," and Mr. Ross's "gentleman's real head of hair," and Jenkins's "patent aperitive fountain," and Captain J. Rhodes Pidding's "royal Howqua's mixture," and Rowland's "incomparable oil macassar," &c. &c.—They have but to get the literal additions to which it is impossible to dispute their title—C.H.A.R.L.A.T.A.N.s, and Q.U.A.C.K.s, to be furnished forth in undeniable fashion, and armed at every point to take the field against the absurdities of professional decency.

But we have travelled a long way from the purpose we had before us when we set out with this notice, which was simply to notify to our readers that the Professor of Surgery in the University of Edinburgh had seen fit to send the substance of his systematic lectures on surgery to the press, and thereby made us Tramontanes partakers of the entertainment he is wont to set before his class. And we beg to say, that we thank him for the pains he has taken.

When we look at the elementary works that are available to the student in the present day, in comparison with those that were accessible to him no more than some quarter of a century ago, we see that he now enjoys immense advantages. In our hot youth, "when George the Third was king," we had such an elementary work to cool our zeal for surgery upon, as Benjamin Bell's "System," in seven volumes 8vo. ! or, reading German, we had Richter's "Anfangsgründe"—a word, by the way, which so tickled our curiosity, that seeing it constantly quoted in Cooper's Dictionary, we learned German in order to understand its meaning—in at least as many tomes. To be sure there was John Bell's "Principles," one of the cleverest and most engaging professional books ever written; but that was inaccessible to the poor student from its price, to say nothing of its size—four vols. 4to. ! In short, there was nothing for us but Cooper's "First Lines"—first lines, indeed, and dry as the remainder biscuit after a twelvemonth's voyage, though spiced by the admirable Dictionary, had the juveniles been recommended to it, but they were not. At the present time the student of surgery has half a dozen excellent works to select from: he has "Liston's Elements"—a book with more learn-

ing than the paucity of quotations would lead one to suspect; Syme's "Principles," an admirable work, terse, sententious, full of meaning, carefully put together, a sure guide; Druitt's "Vade Mecum," an unsurpassable compendium, not only of surgical but of medical practice. And then, for the manual department and much more besides, he has Liston's "Operative Surgery," and Fergusson's "System of Practical Surgery"—both works of the highest stamp. Finally, he has Professor Miller's "Principles." We do not venture to direct the student's choice. Men are sufficiently apt to think the last the best, particularly in science; and it is certain, indeed, that he who has the mind and science which we look for in a teacher at the present day, has always an advantage over his predecessors. Although there are several works, then, of the same scope and purpose as Professor Miller's, we are pleased to have it; as an improvement, we will venture to say, upon all that has gone before it, we bid it welcome.

The work is manifestly calculated for the student, not for elderly gentlemen who wear glasses. Having, nevertheless, in discharge of our critical duties, to look into its pages, we have been led unconsciously somewhat to strain our eyes over them; for, in truth, we found the matter so pleasantly put together, that we were induced to refresh our memory upon more than one point of practice, and to ascertain whether any change had come over the spirit of chirurgery since we listened to John Thomson in the north, to John Abernethy in the south, and to the venerable Baron Boyer on the other side of the channel. No question about it, science, surgical science, has advanced; and we are well pleased to have lived in times that have done so much to clear up fundamental principles. The theory of surgery but few years ago was a chaos in spite of the vaunted labours of Hunter; and despite of all that Thomson gathered on inflammation, no mortal knew what inflammation was. At the present time all is order, and harmony, and light; and the labour of learning, despite the accumulation of materials, has become vastly less than it was. In the inductive sciences individualities extend, generals shrink, or the new individual

is absorbed without his presence being perceived; he is but one of the rank and file; he stands up before us among the 100,000 men all clothed and accoutred alike, obedient to the same command, apt to discharge the same offices, needing no particular attention; and so it comes to be strictly true, as Monsieur Pibrac said long ago, that "Nous perdrons une grande partie de notre savoir, si nous étions débarrassés de toutes nos erreurs;" a conceit, or sentiment, which Mr. Abernethy translated in some such way as this: "Increase of knowledge is like increase of nothing else; it is attended with a shrinking in the mass." The seven volumes 8vo., the four volumes 4to., are shrunk into a single post 8vo. volume of some 700 pages; and yet these contain more of positive information than the collected 3,500 8vo., or the 2,000 4to. broadsides that preceded them. Professor Miller, from his position and experience, had a title to come before the world as the author of an elementary work. We are happy to be able to say, that, in our opinion, he has written an excellent one.

The book is inscribed to Mr. Liston, who may be said to be the professional parent of both the professors of surgery, in the University of Edinburgh; Mr. Syme, as well as Mr. Miller, having been his pupil, and having also dedicated his book to his old friend and instructor.

MEDICAL GAZETTE.

Friday, October 18, 1814.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medice* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO

THE MEDICAL PROFESSION BILL.

THE REGISTRATION OF STUDENTS CLAUSE;
THE CONSTITUTION OF THE EXAMINING
BODIES, AND THE EFFICIENCY OF EXAMINATION CLAUSES.

It is obviously intended by the framers of the Bill that the Council of Health and Education shall be supreme; it will have more power over its subordinates than is possessed by any other assembly or convocation of individuals in this country, unless it be the House of

Commons in parliament assembled. Clause the 22d enacts that no bye-law to be made by any of the Royal Colleges of Physicians or Surgeons of England, Scotland, or Ireland, shall be of any force until a copy thereof, with the seal of the College propounding it, shall have been laid before and approved by the Council of Health and Education. We do not know that this was very necessary; we own to the infirmity of liking to see men left to govern themselves. True it is, the bye-laws of some of our medical Colleges have sometimes been indifferent enough; but it is an experiment to be made whether they will be any better with the revision of the central Council; with our free press and open discussion we have long ceased to be afraid of any iniquity being committed and persisted in; redress was always had at last. The Council of the Royal College of Surgeons in London, responsible to nobody, would never have ventured to do what the Royal College of Surgeons of England have done in conformity with the provisions of the New Medical Bill.

Clause 23d authorizes the Council to make regulations for registering the medical and surgical students by the proper officers of the several hospitals or medical or surgical schools at which they study, who may exact a fee for such registration not exceeding ten shillings in each case, the fee to be remitted to the secretary of the Council of Health and Education, and to be applied towards the expenses of the Act. Returns are farther to be made to the Council of the students, in such manner and form as the Council shall direct; and no hospital or school shall be recognized by any of the licensing Royal Colleges which shall neglect or refuse to give due effect to such regulations as the Council may make.—All who have experience of medical students will see the propriety, the necessity, of some such regulation as this—

verily as we come into close contact with the practical clauses of this Bill we begin to be somewhat in love with it—we would willingly excuse something that we think might be better—and who knows but that by labouring zealously and candidly at the measure, we may get what appears amiss in it made better? for that which we freely admit to be excellent in its provisions. The system of registration must be very different from that pursued at present at Surgeons' College and Apothecaries' Hall. There, it is notorious that the young men sign for one another; and not unfrequently the signer is in London only for the day on which he signs. We have heard a friend speak of the exultation and amazement he experienced the first winter he lectured, at the number of students who signed upon a requisition from the College of Surgeons for a return of the students attending each class; he thought he was to deliver himself upon his unpopular subject of Practice of Medicine to crowded benches, instead of to ten or a dozen. He soon discovered his mistake: the gentlemen registered; they did not mean to attend; and the lecturer by and by lost caste for ever, by refusing to sign certificates of regular attendance for individuals whom he had never seen since the signing day at the beginning of the session, till its approaching close. The Council of Health and Education must be warned upon this point; if they can devise machinery to make regular attendance upon lectures imperative, to secure the presence of students in the lecture room, and to free the lecturer from the odious business of setting his name to what he knows not to be true in almost every alternate instance, at some schools, they will do much, very much, to advance the science and the practice of medicine in this country. The vast amount of labour bestowed, and of thought expended, by lecturers on the

several branches of medicine, is unimagined by all, save the individual who has gone through the arduous duties of the teacher. If the Council approve of attendance on lectures being required, let them also secure that attendance be given. The teachers themselves cannot do this.

It strikes us that there is one important omission in this Registration of Students Clause; it is, that no information is taken as to previous study. But we hold it of the last importance that he who is to be the future practitioner of medicine, should, in the first place, be the liberally educated man. We would have an examination preliminary to registration, made imperative, to which none should be admitted who had not completed his 17th or 18th year. This we are disposed to look upon as the first and most essential step to be taken, in any attempt to raise the character of the medical profession. If the framers of the bill thought an inferior class of practitioners necessary to meet the wants of the labourer and artizan—which we do not—we would still entreat them for the preliminary examination from the aspirant to the higher grade—from him who aimed at the dignity of Physician or Surgeon. But probably this is held matter of detail, and is left to the licensing colleges to require: we, for our part, esteem it of such vital importance, that we should have been pleased to have seen it forming the subject of a distinct clause in the Bill.

The 24th clause provides that where the concurrence of more than one body is required for qualifying parties for registration by the Council, the examination may take place either separately before examiners appointed by each body, or before a joint board of examiners to be appointed by each body separately or conjointly, in such number, manner, and form, and at such times and places, as the bodies, with the ap-

proval of the Council, shall agree upon among themselves; further, the fees of examination are to be divided between the bodies in such manner as they may agree upon among themselves, or, in case of difference, as the Council shall determine on with respect to any point upon which they shall not be agreed.

As we interpreted the Bill at first, and looking only at an early clause, we did not observe this provision for harmonious or simultaneous working between the candidate and the several examining bodies—we make the framers of the bill the amende, and own to our short-sightedness.—Surely an efficient and fair examination ought to be the result of what may be called open questioning by gentlemen members of, and appointed by, two distinct royal Colleges, in presence of each other. No question will be propounded that ought not to be answered; no one, failing to answer examining bodies so constituted, will think himself unfairly dealt by when he is referred back to his studies.

The division of fees is another important element in this clause. It is its wealth that has enabled the Royal College of Surgeons of England to strengthen itself with its magnificent museum and numerous library; it is its poverty that has prevented the Royal College of Physicians from doing aught in the same direction for the accommodation of its Fellows and Members, and that leaves it even at the present hour without other hold upon our consideration and regard than it has from its antiquity, from its historical associations, and from the learning and character of its individual associates. With the fees of licentiates divided between it and the College of Surgeons, the College of Physicians will be able to do much more than its funds have yet permitted it to accomplish; it may by and by have a pathological collection second to none in Europe, and a library equal to the one in Lincoln's Inn Fields. The profession, instead of

one, will thus have two grand repositories of facts—that is, of experience—to appeal to; and if the accumulated experience of mankind be of any value, who shall say that this will not conduce to the best ends? We see wider and better prospects for our profession in this wise and excellent provision.

The 25th clause provides for the efficiency of the examination, and need not detain us. It is good,—always admitting the supreme authority of Council to be good, which we are inclined to do in the present instance. The examining bodies are to make returns to the Council of the particulars of their examinations, at which any Secretary or any member of the Council may be present.

MOVEMENT IN THE PROFESSION.

WE do not profess to keep, or to render, an account of every meeting that takes place throughout the country on the subject of “The Bill.” Those of which a notice by the means of a provincial paper is sent to us, however, we have hitherto noticed again: these meetings are, in fact, the best feathers the Minister can have by which to know how the professional wind sits.

On Tuesday, the 8th inst., the members of the medical profession residing in Salisbury and its neighbourhood, met in the Council Chamber of the County town, Dr. Grove in the chair, when the sentiments expressed were a good deal marked by distrust and doubt. Whilst the meeting hailed such portions of the bill as are calculated “to increase the influence of the profession and improve its character, it cannot but regard with a feeling of regret and disappointment those general principles which remove all restrictions from the practice of medicine, as a measure most dangerous to the public, and most prejudicial to the best interests of the profession.”

A petition to parliament was agreed on, to the effect “that although the meeting regard with satisfaction some of the provisions contained in the projected Bill of Sir James Graham, yet as a whole they view it with disappointment, disapprobation, and alarm. While

it professes to protect the medical profession and public health, they believe it to be directly and most grievously injurious to both. That it offers direct encouragement to empiricism with its enormous and incalculable evils, tends to degrade the educated and legalized practitioner, and to discourage and retard medical science.”

On Thursday, the 10th inst., a numerous meeting of the profession was held in the Theatre of the Philosophical Institution, Bristol: Mr. Mortimer in the chair. The chairman in introducing the business said “He thought that they would all agree with him that the object of Sir James Graham was to benefit the profession, by raising the standard of education, and thereby raising the general respectability of the whole profession; that was avowed in the preamble; and he thought that they would also agree with him that they should discuss it with calmness and good temper. The Government in this bill had shewn a disposition to grapple with the subject of reform, in trying to remove some of the anomalies connected with the practice of physic and surgery; and it would now be their fault if they did not assist it in making the bill as perfect as possible, as the government had purposely given them that opportunity, by leaving it on the table of the House just previously to the recess, and thereby soliciting the opinion of the profession upon the subject: for this courtesy they were much indebted to Sir James Graham. The Council of Health and Education was an important clause in the new bill, wherein the Government retained the power of forming a large portion of its members by the crown. The register, also, of all licensed practitioners under the titles of physicians, surgeons, or licentiates in medicine and surgery, appeared in its general character very good; but the penal clauses were insufficient for their proposed end, and left those who had passed the ordeal of strict examination, without protection against the unprincipled quack and the ignorant pretender.

Dr. Symonds—and we make a point of quoting every word that a man so distinguished said on the occasion—in rising to propose the first resolution, “begged to state that he should not have taken any part in the present meeting had he not been apprised previously that it was intended that it

should be conducted in a conciliatory spirit, for he thought that the profession generally were greatly indebted to Sir James Graham for having introduced the measure; and he certainly was the first Minister of the Crown who had brought forward such an important and general measure for the reform of medical practice. In doing so there could be no doubt but that he must have had great difficulties to contend with; but he certainly thought that as a whole the bill had been carefully framed. As regarded that portion of it which constituted a Central Council of Health, to whom appeals might be made, &c. he thought there could be but one opinion as to the great advantages which must result from the appointment of such a body; there could also be but one opinion as to the register of qualified practitioners: still, however, while he confessed his approval of the bill as a whole, he was not blind to its faults, the principal of which was the want of proper protection for the legally qualified practitioner. He thought that they ought to demand such protection, and that the ignorant, unqualified, contra-band practitioner, should be subject to penal enactments. He knew that it might be said that the register was open to the public, and that the public thus had their choice of qualified practitioners: it might also be said that it would be contrary to the recognised liberty of Englishmen were they not allowed this choice, for if they were foolish enough to apply to improper persons they suffered death for their folly. This was not, however, the question; for was it right that our Government should allow any ignorant empiric to practise? was it justice for the Government to encourage imposture? was it correct that the public health should be subjected to ignorant pretenders? He did not think that they ought to go before the Government with an *argumentum ad misericordiam*, but he did think that the course of education which they had to go through previously to their entering the profession, and the toils they had to undergo in its practice, entitled them to something beyond mere justice; that it entitled them to protection in the exercise of that profession which it had cost them so much toil and expense to acquire. He was sure that every one present knew that the

medical practitioner had to toil from early dawn to dewy eve, and frequently lost his rest for perhaps three nights in a week, and for which, if his remuneration at all equalled that of some persons who were employed in solely ministering to the artificial tastes of mankind, there was an immediate outcry that he was realising a wonderful income: too often, however, the medical man received but a scanty remuneration for his anxious care, and the important services which he rendered the public."

Various resolutions in harmony with the spirit thus evinced, and laudatory of the Company of Apothecaries, were passed.

At the Meeting at KENSINGTON, — Mr. Merriman in the chair, — Mr. Godrich, in moving the first resolution, said the bill would, he was confident, afford no real protection to the profession; that, in fact, it was an attempt to lower the general practitioners; that it tended to separate the duties of the surgeon and physician, which he disapproved of, and to throw open the profession to every charlatan. The first resolution was to the effect that the repeal of so much of the act of 1815 as prohibits any unlicensed person from practising, without substituting some other protective enactment, would be productive of serious evil both to the public and general practitioner.

Dr. Ogier Ward moved the second resolution, which characterized the constitution of the Council of Health, without any representative of the body of general practitioners, as most unjust, and derogatory to the class.

The third resolution was moved by Mr. Wooley, and was to the effect: "That this meeting cheerfully bears testimony to the satisfactory manner in which the Society of Apothecaries have carried out their act of 1815, as evinced by the high standard of medical education which they have established. And further, that it is the opinion of this meeting that the regulations relating to the medical education of the general practitioner, and the medical examination as to his efficiency, should be committed solely to members of his own grade, which has for nearly 30 years so ably performed those duties, and rendered thereby such essential service to the country and the profession, and not, as proposed by the bill, to persons whose interest it may be to lower the

standard of education, and lessen the efficiency of that branch of the profession."

Mr. Pollock proposed the fourth resolution, which was as follows:—"That while this meeting agrees in the propriety of having a general registration of all the legally qualified medical practitioners, it must object, first, to a tax being laid upon men who have already been put to a great expense in paying the admission fee of the existing medical corporation; and, secondly, that the registration clauses do not effectually preclude by their penalties the influx of uneducated and disqualified men into the profession."

The cordial thanks of the meeting having been voted to the *Times* and Mr. Wakley, for their powerful advocacy of the principle of protection to the public health, the meeting separated.

This was obviously a meeting actuated by a very different spirit from the Bristol meeting. It was what may be called a radical meeting.

We have, farther, notices of meetings held at Wrexham, where the usual resolutions were passed, and a petition adopted, from which the following is an extract: "That as, in framing the proposed Bill, it has been considered expedient that certain qualifications shall be required in those Members of the Profession who may be appointed to any public situations, your Petitioners would humbly submit to the consideration of your Honourable House the necessity of affording to the public in general, in the far more extensive field of private practice, the same protection which has been very wisely thought necessary for inmates of Hospitals and Workhouses."

There was also a meeting at Woolwich on the 11th, at which it was resolved unanimously to petition the House of Commons against several objectionable clauses contained in Sir James Graham's Bill.

POISONING WITH RADIX SAMBUCI.

A WEAKLY woman, 54 years of age, who had been sick all day, and thrown up a quantity of greenish stuff, which she regarded as bile, was persuaded by her husband to take two table-spoonfuls of the juice of the fresh elder root, which he himself had dug up, shaved down, and pressed. The woman complained of severe pain in the abdomen. She was ordered some infusion

of senna, but did not take it, as the bowels began almost immediately to act copiously. Next day the symptoms were those of enteritis: paralysis of the lungs followed, and the patient died. The body was not opened. —DR. SCHOLLMEYER, *Medicinische Zeitung*, No. 8, 1844.

NOTE FROM MR. GAY.

To the Editor of the Medical Gazette.

SIR,

IN a late number of a cotemporary journal, Dr. Costello has announced me as one of *his colleagues*. May I be permitted to state, through the medium of your journal, that I am not a colleague of, nor in any way whatever connected with, that gentleman.

I have the honour to be, sir,

Your obedient servant,

JOHN GAY, F.R.C.S.E.

Surgeon to the Royal Free Hospital, &c.

12, Pavement, Oct. 14, 1844.

APOTHECARIES' HALL.

Gentlemen who have obtained Certificates, Thursday, October 10. — W. P. Beloe, Lynn Regis, Norfolk. — W. Leapingwell, Good Easter, Essex. — H. James Stokes, Rochester, Kent. — W. Cholmeley, Wainflete, Lincolnshire. — S. J. Remnant, Tavistock Square.

MORTALITY OF THE METROPOLIS.

SUBSTANCE
OF
CLINICAL LECTURES

DELIVERED BY MR. STANLEY,

*At St. Bartholomew's Hospital, during the
Summer Session 1844.*

*Treatment of Transverse Divisions of the
Larynx and Trachea.*

THE rule of practice usually observed in the treatment of these injuries, is to trust to position alone for the approximation of the divided structures. The following cases, of recent occurrence in the hospital, have conveyed to us the practical lesson, that other measures may be requisite to counteract the retraction of the lower portion of the larynx or trachea, consequent on a free division of either structure in the transverse direction.

An elderly man passed a razor across the thyroid cartilage, the lower portion of which retracted freely, leaving a wide aperture in the front of the neck, through which the ventricles of the larynx and ligaments of the glottis could be plainly recognised. No sutures were used. Position alone was relied upon as the means of approximating the divided parts. With the head and neck inclined downwards and forwards, the edges of the wound in the skin came readily into contact, and it was expected that with the healing of the soft parts around the larynx, the two portions of the thyroid cartilage would gradually approximate; but it proved otherwise. The integuments cicatrized around the divided edges of the thyroid cartilage, but its lower portion remained firmly fixed in the depressed position. During the cicatrization of the integuments, the aperture in the larynx contracted in some degree, but it was still considerable. After several months had elapsed, as no further change was apparently going on in the parts, various suggestions were offered as to the means likely to raise the lower portion of the la-

ryn timer, and to close the aperture in it. So firmly fixed were the two portions of the thyroid cartilage by the cicatrization of the soft parts around them, that it did not appear probable that these objects could be attained by means of sutures passed through the portions of the thyroid cartilage, in the view of drawing them together. The only available suggestion was, to separate the firmly cicatrized tissues from the lower portion of the thyroid cartilage, in the hope that when thus liberated it would rise to its proper position. I determined to try this plan, but had proceeded a very little way with it, when I discovered, close to the wound I had made, the pulsations of two large arteries, which I presumed to be the superior thyroids, the division of either of which might be expected to cause serious mischief, from the blood flowing into the larynx. Consequently, I desisted from any further operative proceeding. The patient left the hospital with the aperture in the front of his neck, through which a little finger could be readily passed into the larynx, and he was unable to articulate distinctly; but this appeared to be the only material inconvenience he suffered.

A woman, aged 62, in a fit of insanity made an extensive wound across the lower part of her neck with a carving-knife, dividing the trachea, and exposing the carotid arteries; it was apprehended, besides, that the œsophagus had been injured, from the circumstance that liquids taken into the mouth directly escaped through the wound, and continued to do so for a few days. The lower portion of the trachea retracting very freely, the wound presented a wide and deep gap in the front of the neck; at the bottom of which could be recognized the glottis above, and the orifice of the trachea below. No sutures were employed; the head and neck were strictly kept in the position favourable to the approximation of the divided parts. The reparation of the soft structures proceeded favourably; but it was observed

that the contraction of the outward wound was not accompanied by any approximation of the upper and lower portions of the trachea; and farther, that a narrowing of the lower orifice of the trachea was gradually taking place, with increasing difficulty of breathing, accompanied by a profuse discharge of thin mucus, secreted by the lining membrane of the trachea and bronchi. The orifice of the trachea became reduced to the diameter of a goose-quill, and thus scarcely permitted the passage of sufficient air for the maintenance of life. Under these circumstances she gradually sunk, and died about two months after the infliction of the injury. On examining the body, it was found that the narrowing of the orifice of the trachea was the result of the thickening and puckering of the surrounding tissues, and that the division of the tube had taken place between its first and second rings; but it did not appear that the trachea had been completely divided; a portion of the mucous membrane at its back part had apparently been left undivided; but it was not sufficient to prevent the lower portion of the trachea sinking deeply in the neck. The lungs were healthy.

The foregoing cases shew the inadequacy of position alone to obtain the approximation of the parts, when the larynx or trachea have been freely divided in the transverse direction, and consequently suggest the propriety of using sutures in the treatment of these injuries. But sutures passed through the soft tissues covering the larynx or trachea will be of no avail; to be effective, they must penetrate the cartilages themselves, or the fibrous tissue which unites them. Moreover, the right time for employing sutures must be chosen. During the first period of the case they are scarcely admissible, from their probable effect in preventing the free escape of the blood through the outward wound; nor should they be delayed to the period when the integuments, &c. have firmly cicatrized around the lower retracted and sunken portion of the larynx or trachea. The following observations have been recorded by Rust of Berlin, shewing that he had observed the difficulties which were met with in the foregoing cases, and that he had, as it appears to me, rightly considered the means of obviating them. Rust observes, that "in wounds dividing only partially the trachea or larynx, a suitably inclined position of the head and neck is generally all that is required to effect a speedy union; but where the larynx or trachea is completely cut across, it becomes expedient to have recourse to sutures. The tendency of the lower portion to sink down from the upper is often so great, that we must not limit our sutures to the cellular tissue, but pass them through the substance of the trachea itself, and even through the cartilages of the la-

rynx." He then relates a case of cut throat which occurred in Charité Hospital at Berlin, where the thyroid cartilage was divided, and adds, "that in this patient, the tendency of the lower end of the divided larynx to sink down from the upper, was such as to occasion the necessity of a suture through the substance of each portion of the cartilage (thyroid), that sutures passed simply through the soft textures repeatedly gave way, and that the healing in this case was perfect."*

In the narrative of the case of the female who divided her trachea with a carving knife, it is mentioned that during the first few days, liquids swallowed directly flowed through the wound in the neck, leading to an apprehension that the œsophagus was injured, which certainly had not occurred. I have noticed this circumstance in other instances of wounds in the larynx or trachea, whether inflicted by the surgeon or by the hand of the suicide: thus, after the operation of tracheotomy, I have seen the fluid which had been swallowed flowing through the slit in the trachea. It would accordingly appear, that a temporary loss of the irritability of the glottis is the consequence of a wound in the larynx or trachea.

Subcutaneous division of tendons.

There are two cases in the hospital well serving to illustrate the variety of circumstances under which the subcutaneous division of tendons may be required.

Talipes equinus in both limbs of an adult, from rigidity and shortening of each tendo-Achilles, gradually arising without obvious cause. Division of the tendons.

A man, 22 years of age, had during the preceding two years felt a gradually increasing inability to walk with ease and firmness. On examining his limbs there was found to be rigidity, with apparent shortening of each tendo-Achilles, which, in the erect posture, prevented his heels resting on the ground. The weight of the body had, in consequence, been chiefly transmitted through the anterior or digital ends of the metatarsal bones, and the feet were becoming deformed, with shortening from the heels to the toes, and deepening of the concavities of the soles. The remedy for this condition of the limbs appeared to be, the section of each tendo-Achilles, in order that, by the elongation of the muscles of the calf, the heels might readily come to the ground. Accordingly I divided each tendo-Achilles; and in a few days afterwards, the punctures in the skin being healed, I placed one limb in Stromeyer's apparatus, and the other in Scarpa's shoe, as modified by Dr. Little; this was done for the purpose of affording to the stru-

* Aufsätze und Abhandlungen von Dr. Joh. Nep. Rust. Vol. ii. p. 222.

dents a view of the mode of action of each instrument, in gradually bringing the foot to a right angle with the leg. The use of these instruments was continued about six weeks, and then a gentle use of the limbs was permitted. By degrees the muscles of the calf regained their power of action; and in about two months after the sections of the tendons the man left the hospital, walking well, with his heels coming readily to the ground.

This case is interesting as an example of shortening and rigidity of the tendo-Achilles in the adult, arising without discoverable cause, and as shewing the talipes equinus thus produced to be curable by the same means as the ordinary cases of this congenital distortion of the foot.

Extreme contraction and immobility of the knee-joints, limited motion of the ankle-joints, consequent on paraplegia; division of the ham-strings, and of the tendo-Achilles in each limb.

This patient is a man 53 years of age: he stated, that about two years ago, he slept in damp sheets, soon after which he felt pains in his loins, and then a numbness in his hips, which gradually extended through his lower limbs, leaving them powerless as far as motion was concerned, and with sensation in some degree impaired; he lost, besides, the power of emptying his bladder, and of retaining the feces. In this condition he was admitted into the hospital; strychnine was given apparently with good effect upon the paralysed parts, but at the same time a large slough formed from pressure in the lower part of his back; on the separation of which, leaving a freely suppurating sore, the condition of the limbs became manifestly improved. He remained fourteen weeks in the hospital, and at the end of this time was able to move about a little, but not to stand firmly. After he left the hospital his knee-joints became gradually contracted and immovable, and continued so to the present time. On his re-admission into the hospital two years after the attack of paraplegia, the following was his condition:—Each knee-joint was immovably fixed in the state of extreme flexion; the ham-strings were contracted and rigid; and the cellular tissue around them had become indurated, and firmly agglutinated to the tendons, whereby their outline could not be distinctly traced through the integuments. Such were the unpromising circumstances of this case. If the knee-joints could be straightened, and mobility restored to them, yet not improbably there had been disease of the spinal cord producing the paraplegia; and if so, of course there could be but little prospect of the muscles regaining their contractile power. So rigid and indurated were the tissues in the popliteal spaces, that, by mechanical force alone, extension of the

knee-joints seemed impracticable. Division of the ham-strings was evidently a necessary part of the treatment; but from the indistinctness of their outline, this could not be so easily done as in ordinary cases. To avoid all risk of injuring the popliteal or peroneal nerve, or the popliteal vessels, I deemed it prudent to divide the rigid ham-strings, and the surrounding indurated cellular tissue, by small subcutaneous incisions many times repeated, in both limbs, applying after each operation the apparatus for extending the knee-joint. Thus I proceeded for many months, very gradually effecting the extension of both knee-joints, and feeling justified in the hope of success by observing that as the joints were slowly straightened, they became moveable, and the muscles shewed no want of power to act on them. As the functions of the knee-joints were restored, it became evident that the action of the ankle-joints was impeded by the rigidity of each tendo-Achilles; accordingly, I divided both these tendons, and afterwards applied Stromeyer's foot-board to each foot. I also divided the extensor tendon of each great toe, as it was rigid, and kept the toe constantly raised. To aid the relaxation of the indurated tissues around the knee and ankle joints, warm baths, with friction of the limbs, were perseveringly employed. The result of these proceedings is, that at the end of eighteen months from their commencement, the man, on leaving the hospital, is able to walk without difficulty. Undoubtedly, but for the subcutaneous division of the contracted tendons, this man would have been a cripple for life; and it is well, again, to notice the fact, that the crippled condition of his limbs originated in paraplegia, complete as far as motion was concerned; and consequently, at the commencement of the treatment, there appeared but little prospect of its success. It may now be inferred that the paraplegia was produced by some other cause than change of structure in the spinal cord.

In the narrative of the first of the preceding cases it is stated that the object in dividing the tendo-Achilles was to obtain the elongation of the muscles of the calf, whereby the heels might readily rest on the ground; this statement may seem to require some explanation; it is founded on the observations of Stromeyer*, and recently of Mr. Tamplin†, concerning the phenomena which succeed to the division of tendons, from which it appears that the new substance between the ends of a divided tendon, like the cicatrix in other tissues, gradually contracts to its tota disappearance, and accordingly that in the examination of the tendo-Achilles at a distant period from its section no new substance

* Stromeyer, Beiträge zur operativen Orthopädie.

† MEDICAL GAZETTE, Sept. 1841.

is discoverable between its divided ends; indeed, scarcely a trace of the cicatrix remains. Another view of the matter might be suggested, that the newly-formed substance so perfectly acquires the characters of original tendon as not to be distinguishable from it. But, from the observations which have been made on this interesting subject, it seems certain that an actual elongation of the muscles of the calf is the consequence of the division of their tendon, and of the treatment subsequently adopted; that the change which ensues is of the opposite kind to that which was first pointed out by Mr. Hunter, namely, the shortening of muscle and the acquisition of a new sphere of contraction in the shortened state, in illustration of which he placed in his museum the biceps muscle from the arm of a negro shortened one-half of its length in consequence of the humerus having been fractured and allowed to unite with "the ends of the bone riding on one another*."

Compound dislocation of the last joint of the thumb. Of the obstacle to its reduction.

In a case of compound dislocation of the thumb now in hospital, the dislocation was reduced without the least difficulty; consequently but little inflammation ensued in the surrounding parts, and there has been scarcely any constitutional derangement. To this case I allude for the sake of the advantageous comparison it affords with two other cases of the same injury which I had in the hospital; one two years ago, and the other during the last summer. The first of these cases occurred in a middle-aged man; the distal end of the first bone of the thumb protruded through a rent in the soft parts on the palmar side of the joint, and the second bone was thrown backwards, its articular end projecting on the posterior side of the first bone, with the skin tightly stretched over it. So much of the first bone protruded through the wound that it was evident the lateral ligaments were torn; the tendon of the flexor longus pollicis was not visible. Efforts were made for a long time, and by every variety of proceeding, to reduce the dislocation, but in vain; no change could be effected in the relations of the parts. On the next day, with a gentle lateral movement of the second bone of the thumb, it slipped into its place. The wound healed rapidly, and the motions of the joint were perfectly restored. The second case occurred also in a middle-aged man, who, when running, fell, the end of his extended thumb striking the ground; the consequence was, a compound dislocation of the last joint, presenting the same characters as the case just men-

tioned. Here, also, every effort was made to reduce the dislocation, but to no purpose; neither by pulling nor pushing the second bone of the thumb could its articular end be stirred from the back of the first bone. These attempts were again ineffectually made on the second day after the occurrence of the injury; and now, in the view of the reduction of the dislocation being impracticable, it was deemed expedient to amputate the end of the thumb, which was done through the dislocated joint. On examining the amputated bone, the tendon of the flexor longus was found to be still attached to it.

Here are three cases of compound dislocation of the last joint of the thumb; one reduced without difficulty, the second, after the failure of forcible efforts, reduced by a gentle proceeding, and the third not reduced at all. And why this difference? it depends, as it has appeared to me, on the position which the tendon of the long flexor muscle happens to occupy; that when this tendon has slipped round either side of the first bone of the thumb to its back part, then becoming placed between the first and second bones, it constitutes the obstacle to the return of the second bone into its place. Moreover, the flexor tendon, when thus displaced, will combine with the extensor tendon in drawing the second bone over the back of the first bone, and in firmly fixing it in this position. Such was the view of the obstacle to the reduction of the dislocation which the observation of these cases suggested. In seeking further information on this subject, I produced, in the dead body, a compound dislocation of the last joint of the thumb, and having turned the flexor tendon around the side of the first bone to its back part, the reduction of the dislocation was then obviously resisted by the tendon: two competent individuals failed to effect the reduction; whilst a third was trying, the tendon slipped into its place, and the dislocation was instantly reduced. Of course, in the living body, the action of the muscles upon the flexor and extensor tendons must greatly increase the resistance to reduction. In the dead body, the likeliest mode of reducing the dislocation appeared to be by keeping the second bone extended, and at the same time giving to it gentle lateral movements which might assist the return of the tendon into its place. In the view that there is a mechanical obstacle to the reduction, which gentle proceedings are quite as likely to remove as forcible efforts, the impropriety of employing such efforts is obvious, such efforts being, it is well known, most severely painful, and occasionally they have been productive of the worst effects. In one case which I witnessed, the repeated employment of force to reduce this dislocation was followed by gangrene of the end of the thumb; in another, by tetanus; and in a third, by loss of life from the

* Physiological Catalogue, p. 1, Royal College of Surgeons.

severe constitutional derangement which ensued.

I have found on record the following evidence in confirmation of the view here set forth of the obstacle to the reduction of the dislocation of the second, and alike of the first joint of the thumb. Mr. R. W. Smith reported to the Pathological Society of Dublin, a case of luxation of the second phalanx of the thumb upon the dorsum of the first. "The head of the first phalanx was forced through the integuments. The flexor tendon was forcibly displaced, and lay between the first and second phalanges. It was evident that reduction would have been very difficult, if not impossible. Mr. Brabazon was apprehensive of tetanus ensuing; he therefore preferred amputation*." Sir George Ballingall has recorded a case of dislocation of the first joint of the thumb; in the narrative of which, it is stated that by forcible extension "the ends of the bone appeared almost disengaged, but could not be made to resume their natural position. The patient was extremely faint, and while in this state, I was pressing gently on the aneal aspect of the joint, endeavouring to push the dislocated bone into its place, when I unexpectedly felt the phalanx slip from under my fingers, and resume its proper situation†."

So many cases have been reported to me of dislocation of the thumb, in which, as in the instance related by Sir G. Ballingall, after the failure of repeated trials with the employment of force, the bones have unexpectedly slipped into their place, that I can have no doubt respecting the course to be pursued in these injuries, which should be, not to employ great force in any mode or direction, but rather to trust to the influence of gentle movements of the parts in effecting the removal of the obstacle to reduction, which I believe to be the displaced tendon of the flexor muscle.

Subcutaneous encysted tumor, containing the acephalocyst hydatid, echinococcus.

I recently admitted into the hospital, a healthy young female, with two subcutaneous tumors, one in the front of the forearm, the other in the front of the chest immediately above the mammary gland. Each tumor was about the size of a shilling, firm, oval, and flattened, and readily moveable in the cellular tissue in which it was lodged. On the first examination of these tumors, doubt arising on the point of their containing a fluid, I pierced each tumor with a grooved needle, when from each, a thick puriform fluid escaped, and accordingly they were considered to be cystic abscesses; that is, abscesses circumscribed by distinct cysts.

Tincture of iodine was applied for some time to each tumor, but with no marked effect. I then decided upon the free evacuation of the contents of the cyst; this was first done with the tumor in the arm, and nothing else was observed to escape from it than a thick, brown, puriform fluid; but from the tumor in the neck, there escaped with the puriform fluid an acephalocyst hydatid of the size of a marble. Free suppuration subsequently took place in the wound, with obliteration of the cyst in which the hydatid was lodged. From the identity in the character of the tumor in the arm with that in the neck, it probably also contained an acephalocyst hydatid, which was cut into in laying open the cyst; and thus it may have escaped through the wound without being observed.

On examining the hydatid which had been removed from the neck, it was found to consist of an opaque, white, globular cyst, filled by a transparent fluid. Also, we observed in the cyst a mass of mucus; on spreading this out between two pieces of glass, and examining it with a moderate magnifying power, we had a perfectly clear view of the curious little worm which has been designated by naturalists, echinococcus; belonging to the class of internal parasites named by Rudolphi cystic entozoa.

The acephalocyst hydatid, it is well known, is not unfrequently found in various regions of the human body in the intermuscular cellular tissue, and but rarely in the subcutaneous tissue. The opaque, white, globular cyst, filled by transparent, probably sero-albuminous fluid, is now regarded by naturalists as the abode of the organized being, designated echinococcus, from one of its characters, the circle of spines or tentacula surrounding its mouth, by which it is supposed to take in its food. The echinococcus has been discovered in a cyst within the liver, also in the urinary bladder of man, but the present is, I believe, the first instance of its recognition in the subcutaneous hydatid.

It will be remarked, that in the case which has been described, a distinct cyst enclosed the hydatid, and hence the characters it presented of an ordinary subcutaneous encysted tumor. This cyst is of course to be considered as in no way concerned in the formation of the hydatid, but as the consequence of the irritation it produced in the surrounding cellular tissue; and to the same cause we may attribute the suppuration within the cyst. In this view of the formation of the cyst, its removal would be presumed to be unnecessary as the means of preventing the reproduction of the hydatid, and experience proves it to be so. I have known several instances of the removal of hydatids by operation from various regions of the body without their enclosing cysts, and the result was perfectly satisfactory.

The subjoined sketch represents the mag-

ON THE PATHOLOGY AND TREATMENT OF OVARIAN DISEASES;

WITH CASES.

BY DR. SAMUEL J. JEAFFRESON,

Physician to the Chelsea, Brompton, and Belgrave Dispensary, &c.

[Concluded from p. 87.]

It is more than probable that the preceding table does not contain all the operations which have been performed; it is to be feared, also, that a natural tendency to publish successful and hold back unsuccessful applications of a new method, may have tended to keep the public in ignorance of some cases of failure, although it must be confessed that the greatest credit is due to those gentlemen who have candidly avowed and described their cases of failure, which, as presenting the causes of non-success, afford beacons of warning to others, and thus present the surest means of advancing the firm and more successful establishment of the very operation on which, by superficial observers, they may be thought to throw discredit. In spite, too, of some pains, I fear that my own table may not be entirely free from errors.

Such, then, as nearly as I can collect,

is the result of 74 ovarian operations. One cannot but be struck at the very first glance with the prodigious proportion—23 out of 74 cases—in which an insufficiency of diagnosis led the operators to attempt that which was in reality impracticable. When such a surgeon as Lizar, backed by all the talent nearly of Edinburgh, has opened the abdominal cavity to remove an imaginary tumor, it cannot be doubted but that many and great difficulties surround this part of the subject; but I must candidly confess, that I believe increased observation and experience, with great care, will for the future render such mistakes proportionately less frequent. This subject is the more deserving the careful attention of operating surgeons, from the fact that the mortality of the whole number of cases is greatly augmented by this source of error; for whilst the mortality was only 14 out of the 51 cases in which the tumors were removed, it was 10 in the 23 in which it was from one cause or other not removed, and consequently 24 in the total number of 74 cases.

As adhesions of the solid tumor or cyst constitute a frequent source of failure, the surgeon cannot be too careful and assiduous in acquiring every means of diagnosis by which he may learn the probabilities of their existence and extent previously to operating; but as these are insurmountable under particular circumstances only, he will do well further to consider, whether any peculiarity in the method of operating will afford him increased facility in overcoming this difficulty. For this, and all other points connected with the mode of operating, inquiry must be directed to the more detailed accounts of each case as published by the respective operators; the objects of my own papers having been, not to instruct the surgeon in those matters which fall exclusively within his province, but to inquire into the general prospects of the operation as a curative means. Without, however, wishing to detract from the merits of other surgeons, it may be right here to draw especial attention to Mr. Walne's "tentative incision;" to Dr. F. Bird's peculiar method, by a moderate incision, so successfully practised by himself; and to Mr. Lane's observations on the advantage of the incision from the umbilicus to the pubes, in this respect

deserve the best attention of surgeons; and it is to be hoped that he will communicate to the profession his experience on this and other subjects connected with the operation. It is worthy of remark, that adhesions, and those too of an extensive and firm character, were present in many of the successful cases.

In comparing this with many other surgical operations, it will be found that, even labouring under all the disadvantages that necessarily surround any new method, its mortality does not exceed, or its success fall far short, of many operations practised and recommended by the best and most experienced surgeons. Such comparison, however, to hold good, must take in the relative natures and risks of the respective diseases, compared with the nature and risk of the operations for their removal. In acute cases—say strangulated hernia and compound fractures, for example—the surgeon, knowing the risks of the disease and the operation, loses not a moment in offering his patient the comparative advantage of the latter; whilst in more chronic affections, as in the instance of stone in the bladder, disease of the joints, and many forms of tumors, such comparison is rendered far more difficult. An operation may speedily rid the patient of his malady, and restore him to health and comfort; or it may, within a few minutes, hours, or days, destroy a life which might otherwise have been prolonged (although with some inconveniences, perhaps) for as many years. It is with this class of operations only that the ovarian section can with propriety be compared.

A disposition seems to exist with some persons to shift off the fatal result of some operations upon other causes. This cannot, I think, be fairly admitted. It is most wise and proper thoroughly to investigate the causes which have led to a fatal termination in any one case, as tending to throw increased light and precision on the after-treatment, and to show how far the disastrous result has been due to previous or subsequent mismanagement, which may in future be avoided, rather than to any thing in the essential nature of the operation itself; and here too, I believe, that the present operation will experience increased precision and success. In this, as in

all other branches of surgery, the dexterous use of the knife constitutes but a part of the art.

The pain and inconveniences of the different forms of ovarian disease, with their risks to life itself, have been already sufficiently discussed, and are, indeed, pretty generally known to professional men; but, unfortunately, no statistical tables of the disease are sufficiently accurate or extensive to enable us to draw an exact average of the duration of life under these diseases. It is, however, to be feared, that rivalry of opinion respecting the propriety of the operation in question, has led one party to over-, the other to under-rate the mortality of these affections. The probable duration of life, and amount of suffering, under the existence of ovarian disease, should be carefully weighed and considered before an operation of so much uncertainty in its result can with propriety be recommended, or even undertaken at the request of the sufferer; and yet it is extremely difficult, from the detailed accounts of operations already performed, to estimate with any accuracy what would have been the result had no operation been performed: some, no doubt, would have speedily fallen victims to their disease; others probably would have lingered on for many months or years in more or less suffering and discomfort; whilst others, again, might perhaps have lived the ordinary term of human existence but slightly inconvenienced by their disease, or might have been fortunate enough to experience a permanent cure under the efforts of nature, or well-directed medical skill. It is therefore much to be regretted that surgeons have not given more explicit accounts of the general conditions of their patients previously to operating, with some surmise as to the probable course of events had no such proceedings been instituted. The value of the operation must be greatly enhanced, both to the operator and the sufferer, when it is felt to have directly snatched the sufferer from the jaws of death, and placed her in a position of health and comfort.

Another point requires to be considered in estimating the value of the ovarian operation; and to this little attention appears as yet to have been drawn. In what proportion of cases

will the cure held good? This is a question of very serious importance; as it appears to me at least. In some few cases the tumors removed have been described as presenting very marked appearances of malignant disease; and it is hardly to be supposed that the removal of the local affection should afford any greater immunity in these than in other cases against the establishment of a similar form of disease in other parts of the system. Dr. Ramsbotham must surely have committed a mere error of expression when, in his valuable "Lectures on the Diseases of Women and Children," he states:—"This appears an operation by no means to be undertaken indiscriminately, *especially as the disease is not of a malignant character.*" Unless malignant disease of the ovaries forms an exception to malignant diseases of other parts, I should conceive that the character of malignancy was precisely that which would forbid the propriety of its removal, rather than form an excuse for the more indiscriminate adoption of such measure.

Short, however, of malignant disease, is it quite clear and certain that, one ovary only being removed, the other may not take on the same form of diseased action, whether consisting in solid depositions or the formation of fluid cysts, or, indeed, in some of the solid forms of tumors, that other and distant parts may not become the seat of similar diseased processes? This question can only be answered at present by mere suggestion, or reasoning from analogy. The ovarian operation has only very recently been performed in a sufficient number of instances to afford the more positive data of facts in answer to this question, and for these facts we have yet to wait. In the interim, it may not be amiss to stimulate the profession carefully to watch those cases in which the operation has been successfully performed; and to regard this important consideration as some check against a too indiscriminate recurrence to this mode of treatment.

In drawing any comparison between the cures obtained by operation with those which are due to other modes of treatment, it must be confessed that the balance will be found greatly in favour of the treatment by the knife; but then, also, it must not be forgotten,

that whilst little or no mischief can be inflicted by careful and judicious medical treatment, the operation has been attended in many instances by great pain and imminent danger, without any advantage being gained,—and in no few even by death itself. The attempt which has been frequently made to compare this operation with that of paracentesis, is evidently unsound; for whilst the object of the former is to remove the disease and restore the patient to health, that of the second is merely palliative, and frequently only had recourse to during the final close of the affection, at the urgent desire of the patient, to obtain some relief to her sufferings, which she has perhaps experienced by the same means at some former period of her disease. It may be, that such relief is bought at the expense of a few days or weeks of lingering and painful existence; but such cannot be regarded as a proper test of the risks of paracentesis.

It may be right, so far as the present statistics of the operation will afford the means, to inquire into the comparative merits of the different modes of operating. A comparison of the success of different operators would be invidious, and into that subject it is neither my wish or province to enter; nor, indeed, are the statistical returns sufficiently extensive upon which to found any very accurate conclusions. In studying this subject, the operating surgeon will do well studiously to look into the motives and results of the plans advocated by his cotemporaries, rather than to encourage himself to regard his own peculiar method as the one which presents all advantages over those of others. It may on inquiry, perhaps, be found that each plan possesses its peculiar advantages, and that the ultimate success of the operation, in the main, will depend upon the appropriate application of different methods to different cases and circumstances.

The table which is here presented to the reader has been divided, as nearly as I could collect, into two great divisions as regards the mode of operating; the one may be designated the major, the other the minor, operation. Such division being founded not on the mere extent of the incision—a matter, however, which cannot be regarded as one of trivial consequence—but upon the

fact, that, in the major operation, the incision is made sufficiently large to allow of the introduction of the hand into the abdominal cavity, for the purpose of placing the ligatures round the pedicle of the tumor or cyst *in situ*; whilst, in the minor operation, the hand is not introduced within the peritoneal cavity, and the cyst, previously emptied of its contents, is drawn out and tied externally to the abdominal walls.

It would appear, then, from the Tables, that the major operation has been attempted in 63 instances, and has been attended by perfect success in 31; whilst the operation has not been completed in consequence of adhesions, the absence of any tumor, mistaken diagnosis as to its real character, or other causes, in 18 cases. The major operation has been followed by the death of the patient in 21 cases.

The minor operation is only applicable, of course, to those cases in which the ovarian tumor is entirely or mainly fluid, and more especially when that fluid is contained in but one cyst, and that of a thin character. For the introduction of this mode of operating the profession is indebted to the ingenuity of Mr. Jeaffreson, of Framlingham; and however future experience and observation may affect the relative propriety of this mode of operating, it would be unbecoming in me to omit this opportunity of expressing my own pride and satisfaction in feeling that the public are indebted to the talent and ingenuity of my relative and namesake, in not only discovering, but actually carrying out, this mode of operation.

The minor operation, it appears, has been attempted in 11 instances; with perfect success in 5. The operation was incomplete, in consequence of adhesions or other causes, in 3 instances; and followed by the death of the patient in 3 cases.

So far, then, as a comparison between 63 cases of one operation, and 11 cases of the other, goes, the results are wonderfully uniform, and leave but little choice so far as respects the method to be chosen; but then other circumstances require to be taken into consideration, which, it must be confessed, turn the scale considerably in favour of the major operation: by the term major operation, however, is not

here implied those prodigiously long incisions, which are probably not required for this form of the disease. The comparison has hitherto been instituted between the major operation, as applied to all cases, and the minor to those only which appeared appropriate to this method. Now, so far as we can collect from the table, the major operation has been had recourse to in 10 cases of entirely, or nearly entirely, fluid monolocular tumors, and has proved successful in 9, and only failed, from the extent of adhesions, in one instance; its employment, under such circumstances, having, so far as can be ascertained by the table, in no case been followed by fatal results. And whilst it is probable that, in some of these 9 cases, the minor operation would have proved inefficient to remove the tumor; it is also fair to believe that the major operation would have been effectual in removing the cysts in some cases out of the five in which its removal was abandoned by the other mode of proceeding.

The most important question remains yet to be considered, namely, how far particular circumstances, judging from past experience, affect the propriety of operating. Many of these circumstances have been already casually adverted to; and it is to be expected that future experience (careful attention being drawn to the subject) will tend still further to clear up this most important point. The necessity for carefully weighing the risks of the disease against those of the operation, not as a whole, but in every individual case, have been already strongly insisted upon; and a hope has been expressed that more careful attention to the subject will tend to increase the precision in diagnosis, the hitherto inadequacy of which has led surgeons to attempt that which could not be completed. It may also be hoped, that an anxious desire to improve by the experience of others may lead surgeons, by adapting their mode of operating to the nature of the case, to overcome many of the difficulties which have too often frustrated the successful completion of this very serious undertaking.

Of the successful cases, 37 in number—

I was common abscess of the ovary (?)
16 entirely or chiefly fluid.

14 of a mixed character, more or less fluid, with greater or smaller solid masses.

6 are not sufficiently described.

Of the cases which proved fatal, although the operation was completed, 14 in number—

1 was fluid and monolocular.

10 were of a mixed character, in which a considerable proportion of solid matter, of various character and hardness, existed.

3 not sufficiently described.

Looking, therefore, at the successful cases alone, there would not appear to be much difference in the choice of cases; but when those cases are also brought into comparison, in which, although completed as regards the removal of the tumors, the operations were followed by a fatal result, there remains a vast preponderance in favour of the selection of the entirely fluid, or almost entirely fluid forms, whether monolocular or multilocular, the advantages of which would probably have been still further heightened had the remaining nine cases been sufficiently described.

Age does not appear to have materially affected the immediate result of the ovarian operation, success and failure having alike been found to attend its performance at all ages. This great difference, however, should not be overlooked, that the advantages derived from a perfectly successful operation in early life are proportionately great as the period of life remaining for their enjoyment. In early life, too, the probabilities are greater in favour of other organs being free from organic disease, excepting, perhaps, in the instance of mixed ovarian tumor of a scrofulous character, or connected with a scrofulous diathesis.

With increased information on the subject, it will be interesting to observe how far previous treatment may influence the result of the ovarian operation. It will be sufficiently evident, that where the operation is recommended or contemplated, the treatment by iodine, mercury, or other powerful constitutional remedies, should not be adopted; or time, at least, should be allowed for their influence upon the system to subside previously to this measure. Friction, electricity, percussion, as recommended by Dr. Ha-

milton, and other local remedies of this kind, should also be avoided under such circumstances, as tending possibly to induce irritation of the solid portions of the tumor and cyst, or positive inflammation of the latter, with peritoneal adhesions. A generally bracing and tonic plan of treatment, so frequently required in all these cases, may be sometimes found, perhaps, to be no useless precursory measure, enabling the system to accomplish the prodigious work of repair which this operation necessarily demands.

Previous tapping has by no means proved a powerful obstacle against the success of the ovarian operation. I suspect, however, for the reasons above stated, when speaking of paracentesis, that the risk of adhesions being formed in consequence of this operation, are far less in the monolocular form of disease, in which the cyst being emptied falls down collapsed into the lower parts of the abdomen and pelvis, than in the multilocular, fluid, or mixed forms of ovarian tumor. It is possible, however, in some instances, that the use of the trocar may be made subservient to the success of the operation for extirpation; where the patient is in too low and exhausted a condition to bear the larger operation, paracentesis may sometimes be rendered available for temporary relief, and afford an opportunity of placing the patient in a condition to take the chance, at a future period, of a permanent cure by the radical removal of the tumor.

With regard, then, to the ovarian operation, I should feel disposed to sum up my own opinions upon the subject to this effect; and in so doing I must beg distinctly to state, that they are opinions only, founded upon my personal observations of the nature of ovarian diseases, and the best statistical records at which I have been able to arrive on the results of operations already performed. It is by no means impossible but that I may have fallen into errors on the subject, and it is more than probable that future observations will materially affect the judgment which I have formed. I have at least endeavoured to obtain such information for the formation of my opinions as was available, and to use that information with candour and impartiality. It is impossible for professional men, without prejudice to their

own reputation, and what is far more important, without detriment to the public good, blindly to rank themselves with the one or the other party; and whatever value may be set upon my own deductions, it will at least be one step gained, if I should have succeeded in a few instances only in substituting conviction from experience for mere prejudice.

1st. It has been sufficiently established, that the extirpation of ovarian tumors is practicable, and that nature is competent to effect the great processes of repair, which so serious an operation demands.

2dly. That as the mortality attendant upon these operations has been shewn to be greatly heightened by taking into consideration the cases in which, from previous errors in diagnosis, the tumors have been found to be other than ovarian; or, being ovarian, from adhesions or other causes could not be removed; increased diligence and attention is required on the part of surgeons to the previous diagnosis.

3dly. That the modes of operating, after-treatment, &c. demand the *careful* and *impartial* consideration of the surgeon, as greatly affecting the possibility of completing the operation, as well as its ultimate result.

4thly. That as whatever future improvements may diminish the risks of the operation, it must ever be considered one of great imminence, it cannot be recommended excepting in those cases in which the bulk of the tumor is productive of much misery and inconvenience; and is already inducing such constitutional disturbance as to threaten some probable limit to the existence of the sufferer.

5thly. That however much assistance he may derive from general rules, the propriety of operating in each case must be decided with a due consideration of the merits and peculiarities of the case in question. A few rash operations must inevitably bring discredit upon the measure, however useful and valuable it may be when conducted with prudence and judgment.

6thly. The fluid forms of tumor are the most appropriate for operation. They are generally the most rapid in their growth, and frequently refill with great rapidity after their evacuation by paracentesis. The risks of adhesion

are less; as also the probabilities of mistake in diagnosis; or of other organs being diseased. Remedies, too, have the least power in the cure of this form of affection. In the monolocular variety, the operation could hardly be recommended, so long as tapping afforded perfect relief, and the fluid was very slow to re-accumulate. The multilocular form of disease is by so much the more appropriate for extirpation, in that tapping is attended with greater risk, and is calculated to afford but a limited degree of relief.

7thly. The mixed forms of tumor are the least appropriate for extirpation; and proportionately so as they contain a greater amount of solid matter. There is a greater risk of adhesions, and also of errors of diagnosis; the opening required for their removal must be large in proportion to the mass of solid. The more solid tumors, if of an inert character, are slower in their growth, and *may* never induce much suffering or risk of life. Their cure is sometimes effected by nature or well-directed medical skill. Their growth sometimes is suddenly arrested, and they continue stationary and comparatively innocuous.

8thly. Somewhat in exception to the last conclusion respecting the more solid but indolent ovarian tumors, it becomes questionable whether their removal may not be sometimes desirable, when their presence has induced ascites. Ascites thus caused can rarely be permanently cured by medical or surgical means, so long as its exciting cause continues in existence; and life will, I believe, rarely be much prolonged under such circumstances. In the 45 cases above related, in which ovarian tumors were removed by the major operation, ascites is actually stated to have complicated 8 cases; in all the ovarian tumors were of the mixed character; and in 6 out of the 8 cases the operations were successful.

9thly. Extirpation cannot with propriety be recommended when the least suspicion exists of the malignant character of the disease; or when it is of strumous origin, and is connected with serofulous disease of other organs, as the absorbent glands, joints, internal viscera, &c.

10thly. In recommending the operation, it may not be amiss to view it as a means of removing an enlarged

growth, which, whether solid or fluid, is producing misery and risk to life, chiefly by its mechanical inconvenience of bulk, or its drain upon the system: hence the surgeon will be alike cautious of operating in those cases in which the local disease, indolent and slow in its growth, produces comparatively little inconvenience and risk; and in another and very opposite condition of things, in which, without his being able to discover precisely the cause, the constitution appears shattered and impaired, in a degree disproportioned to the extent and importance of the local disease. In such cases, there is too great reason to fear that there is more mischief going on in the system than would be removed with the extraction of the ovary. The cases No. 4 and 6, as related above, are to this effect, in which it is hardly reasonable to suppose that the removal of the ovaries, even at an early stage of the disease, would have long retarded their fatal termination.

22, Half-Moon Street,
Sept. 1844.

CONTRIBUTIONS

TO HYGIENE, WITH PARTICULAR REFERENCE TO THE SOLDIER.

MILITARY HYGIENE.

Punishments; their Moral and Physical Effects.

THE object of hygiene is to preserve health and prevent disease; when the health of soldiers is specially concerned, it is termed military hygiene. This branch of military medicine is founded upon a knowledge of the causes which either promote or impair the health and efficiency of troops. Vaidy, in an article entitled "*Hygiène Militaire*," in the *Dictionnaire des Sciences Médicales*, has given a very minute account of the different subjects comprehended under this topic, from which the following heads of chapters have been selected—namely, composition of an army, recruiting, diet—including beverages of different kinds, clothing, cleanliness, equipment, arms, barracks, hospitals, habits of soldiers, military discipline, military punishments, marching, mean ratio of sick, medical officers, sieges, battle, or actual conflict with the enemy, duties of medical officers in the

field, cantonments after a campaign, embarkation of troops, climates—tropical and temperate, discharging of disabled soldiers, asylum for invalids; with an account of the general principles of military statistics and medical topography, and instructions to young medical officers respecting the best mode of executing the various duties which they may be called upon to perform.

The French language is rich in works upon military hygiene; while we have no comprehensive or satisfactory publication upon that subject in the English language. In the present contribution I intend to confine myself to a few desultory observations on punishments; and if I should be so fortunate as to excite others to publish the result of their experience upon some of the various topics included under the head "Military Hygiène," I shall be much gratified.

It is universally admitted, that an army without discipline is nothing better than an armed mob, which is more dangerous to its friends than its foes. To maintain due control in the British army, to check military delinquencies, and enforce obedience, it has been deemed expedient to employ terror-striking punishments of various kinds.

Punishments may be divided into two great heads, namely, corporal or physically afflictive punishments, and mental or ignominious punishments. Corporal punishments had no doubt their origin in a feeling of revenge or retribution; but this barbarism has been greatly mitigated by the benign influence of christianity and the progress of civilization, and pain is now inflicted chiefly as a means of reformation, or as a warning to others not to follow the example of the delinquent. But it may still be asked, are the means usually employed to preserve order in the army, the most humane that might be adopted, not only with safety, but with advantage? Have severe and degrading punishments been effectual in preventing crime? Are not sound policy and humanity not only compatible, but inseparable? When we look at the returns of punishments inflicted, it can hardly be concluded that the means hitherto adopted to promote discipline in the army have been very successful. On an average, about 20 per cent. of the troops serving in the colonies and

foreign dependencies are annually convicted by the sentence of a court martial, and punished. "Habitual drunkenness" constitutes about two-fifths of the whole number of convictions. "Desertion," and "absence without leave," are the most prevalent crimes among troops employed in Great Britain and Ireland. In 1839 no fewer than 2110, being nearly equal to one-fifth of the number of recruits annually raised, were convicted and punished for these two offences.

The frequency of delinquencies in the army has been commonly attributed to the circumstance, that it is recruited from an inferior class of the population; by which means uneducated and low-born persons are admitted into the ranks. How far this surmise is well founded, it is difficult either to prove or to disprove. Considering, however, the unfavourable opinion entertained by the public in regard to the army, the onerous duties and thralldom of soldiers, and the limited remuneration they receive for long and arduous services, I do not think a more prudent and better class of men are likely to become soldiers.

The British army consists of two very distinct classes, namely, officers and soldiers. One class is trained to command, and the other to obey,—obedience being the most essential element in military discipline. Recruits, in general, enlist without consideration, and enter into an indissoluble contract, respecting the nature of which they are for the most part totally ignorant. Most of them enlist from mere thoughtlessness and domestic broils; some from misery or want of the means of sustenance, which may arise from idleness, or from the difficulty of procuring suitable employment; and not a few from temporary inebriety. In the course of time the soldier perceives the barrenness of his situation, and the never-ending nature of his engagement. He frequently sees men, not his superiors in talent or merit, rising to wealth and distinction in the world, while he feels that he is stationary for life, and that his prospects are not likely to mend. He may, and no doubt frequently does, overlook the numbers who fail, from having fallen victims to misfortune and poverty. It need not therefore surprise us, that men constantly suffering under

the irksomeness of military restraint, unrelieved by any variety of amusement, occupation, or encouragement, and conscious that good conduct leads to no adequate reward, should evince impatience at the severity of discipline, and endeavour to liberate themselves by desertion, having no hope of obtaining freedom, within a moderate period, by any other means.

The crimes of soldiers chiefly arise from the constitution of their profession. To disregard the verbal order of a commissioned officer, or even of a non-commissioned officer—a corporal, for example—is insubordination, and renders a man as liable to be tried by a court-martial, and punished, as if he were to commit a breach of the mutiny act or the articles of war. Soldiers are also liable to be punished for constructive offences, such as alleged disrespect to a superior officer. It is difficult, therefore, to escape from the net of military law, its meshes being closed against the exit of the minutest fry of delinquencies. A court-martial may sentence a soldier to suffer corporal punishment, not extending, however, to "life or limb, for immorality, misbehaviour, and neglect of duty." The vague generalities of this article literally annul the benefits of a written code. The Chinese have a similar article in their code of laws. It is as follows: "Whosoever is guilty of *improper conduct*, and such as is contrary to the *spirit of the laws*, though not a breach of any specified article, shall be punished at the least with forty blows." In such cases the will of the judge or court is the law.

Well-educated persons, individuals whose parents belong to a respectable class of society, and who have undergone careful moral training, find the thralldom and usages of the service as irksome, and are as liable to military "misbehaviour," as the uneducated and low-born class of soldiers; perhaps they are, indeed, more liable to fail in respect to their immediate superiors, whose conduct they may consider arrogant or oppressive. Implicit, unquestioning obedience, is an indispensable requisite in every soldier, according to the institutions and customs of the army; and this is perhaps more irksome to well-informed men than to the uneducated.

When so much is left to the arbitrary will of officers, in regard to the delinquencies of soldiers, it will appear that the welfare and happiness, and I may add the efficiency, of a body of troops, will be greatly influenced by the discretion, good sense, humane disposition, and experience, of a commanding officer. Every one admits that the poor ought to be educated; but it is of more importance that the rich—in other words, those in high station—should be well instructed; for if their principles were right, and their practice wisely conducted, the institutions and customs of society would eventually be somewhat purified and improved. The doctrine of expediency, and the plea of custom, regulate weak minds; and however well-intentioned routine commanding officers may be, they are liable greatly to abuse the power with which they are invested.

It has been asked by an apologist for corporal punishment, as there is no encouragement, or next to no encouragement, for good conduct in the army, how can you abolish (flogging) the punishment necessary for repressing bad conduct? But it may be asked in return, is flogging calculated to render an "ill paid and ill rewarded" soldier well conducted and obedient? Will punishment induce him to like the army, and to prefer it to the condition of civil life? And does not sound policy, as well as honesty and humanity, forbid us to punish delinquents until we have tried the requisite practical means to prevent the commission of crimes? and, I may add, unless that punishment promises to be beneficial?

Experience seems to prove, that crime is more effectually prevented in civil life by the diffusion of information, good moral training, kind treatment, and an easier mode of gaining a livelihood, than by the most severe punishments. May we not therefore presume, that offences may be prevented in the army much more effectually, by raising the character of soldiers, and by meliorating their condition—by making them, in fact, prefer the public service to the situation of labourers, or artisans in civil life—than by either corporal or mental punishments? By examining the circumstances attending individual instances, which, like a mirror, reflect

the deformity of corporal inflictions, we shall find that severe and ignominious punishments neither reform delinquents, nor operate beneficially as exemplary penalties.

Among the numerous and important subjects connected with the punishment of military offences, the nature of the punishments themselves demands attention. Capital punishment has hitherto been considered a necessary and unavoidable evil, which, with all its dreadful preparations, and the terrible ceremony of the execution itself, is retained less for the punishment of the criminal, than as a warning to others not to follow his example. But whether we have a right to torture, and finally put to death a criminal, in order to deter others from repeating his offence, may be doubted. It has been often observed, that extremely severe sentences, such as capital punishments, defeat their own object; they certainly fail to prevent desertion.

During the American war of 1813, desertions from our army to the United States were frequent; and to prevent this, men who were caught in attempting to cross the boundary line were executed: six were shot in one day, but without any beneficial effect. In order to show with what indifference individuals met death, and by inference how little influence this punishment had in preventing crime, the particular circumstances which attended the execution of one man may be stated. "A private," says Colonel Campbell, then Brigade Major of De Meuron's regiment, "was to be executed. The troops were formed in three sides of a square; at the other side, towards the forest, the grave was dug, and the coffin for the criminal to kneel upon was placed, as usual upon such occasions, beside it. The provost, with the firing party, escorting the prisoner, and with the band of the regiment at their head, playing the Dead March, entered the square,—when, to my surprise, there proudly marched the prisoner, coolly smoking a cigar. Seeing the bad effects likely to result from such evident contempt of death, painful as it was to me, I called the provost, and ordered him to take away the cigar from him. On approaching the grave, the prisoner walked quietly but steadily forward, looked

into it, and turning round to me, said in French, 'It will do.' He then walked up to his coffin; and before I was aware of what he was about, with his middle finger and thumb he measured its length, and turning round to me, he said in French, which his corps generally spoke, 'It will do also.' He refused to permit his eyes to be covered, pushing the provost aside, and exclaiming in French, 'I am a brave soldier, and have often looked death in the face, and shall not shrink from it now.' The provost made signs to him to kneel upon his coffin, but he replied, 'I prefer standing, and shall do so firmly.' The party fired, and in an instant he ceased to exist."—(*A British Army as it was, &c. by Lieutenant Colonel James Campbell*, p. 95.)

This mode of executing the sentence is liable to some serious objections, more especially on account of the circumstance that a prisoner may be pierced with a number of balls without ceasing to live. When Placido, the chief conspirator of an insurrection in the island of Cuba, was executed, five balls entered his body. Amid the murmurs of the horror-struck spectators, he rose from the bench upon which he was sitting, and turned his head towards the soldiers, his face wearing an expression of super-human courage, "Will no one have pity on me?" he said. "Here (pointing to his heart), fire here." At that instant two balls pierced his breast, and he fell dead. Nineteen insurgents were shot at the same time with Placido.

In illustration of the strictness of military law and military usages, when compared with the laws which regulate civil society, I have subjoined an account of the execution of a very remarkable man.

Private Flanagan, — regiment, was a fine looking soldier, about six feet one inch in height. He had excellent natural talents, and had received a tolerably good education. He had acquired a knowledge of Latin, and could speak the French language. When the regiment went to India, he was in a short time able to communicate with the natives in several of the languages of the country. Although Flanagan was a smart clever soldier, he was liable to commit slight breaches of military discipline, and his name

was consequently sometimes entered in the defaulter books. Being a man of high spirit and violent temper, he could ill bear the reproaches of the adjutant, who repeatedly censured him for his irregularities. On one occasion he became so irritated with the rebuke he was receiving, that he impatiently pushed the adjutant from him with the back of his arm. Flanagan was forthwith tried by a court martial for offering violence to the adjutant, and sentenced to suffer death. When the sentence was communicated to him, he simply observed that he thought the award of the court was severe. On the day of the execution he preserved the most remarkable firmness, and conducted himself with the strictest decorum. The square having been formed, he, by permission, addressed the company to which he belonged. Having reached the fatal spot, the fort-adjutant commenced to read the proceedings of the court martial; but having lost self-possession, his tongue faltered, which being observed by Flanagan, he addressed him by saying, "I see, sir, that you are agitated; pray allow me to read the proceedings for you." No notice was, of course, taken of this offer. He then begged that he should not be blindfolded, and that he might be permitted to give the word of command to the execution party; both of which requests were granted. He finally gave the word of command, with as firm a voice as a serjeant-major is accustomed to do on a drill parade.

Flanagan's untimely fate took place in June 1828, at Trichinopoly—he having, in all probability, fallen a victim to the unwise, injudicious, and harassing treatment of a superior officer. How far it was beneficial to carry the capital punishment into effect in this case, it is not for me to give an opinion. The crime appears to have been the result of momentary passion or irritation, not a consequence of design; and perhaps he was hardly sensible of the breach of discipline he committed in the act for which he suffered death.

Another example, which occurred lately, on a foreign station, may be given for a similar purpose, namely, to illustrate the rigour and practice of military law. Private H—, belong-

ing to the — regiment, was brought before the captain of his company for having been drunk, and ordered the trifling punishment of two or three days' drill, when he gently struck this officer's shoulder, exclaiming at the same time, "There now is death for me." The man in question was of highly respectable extraction, and a graduate of one of the English Universities. He drew up what he intended as a defence, but was dissuaded from the avowal of the sentiments and disclosures it contained, by some benevolent persons, who thought it might operate against him. The purport of what he intended to express was this: that he had been suspected of writing a letter in a newspaper, respecting the state of the regiment, some two or three years ago, and that he had ever since undergone such unremitting persecution, as rendered life intolerable, and he therefore, by the commission of this crime, hoped for death, as a termination to his sufferings. He did not name any one as his persecutor, but intended merely to remind the court, that rational beings were not in the habit of acting as he and others had done, without some cause. This man was sentenced to *eight years' imprisonment* with hard labour, and a month's solitary confinement every four months.

Had private H— committed suicide, instead of making a shew of striking his captain for the purpose of being put to death, a coroner's inquest would, I think, have returned a verdict of *temporary insanity*. It is notorious that this man sought death as a release from continued suffering. The mind becomes unsettled from mental anguish; and whether we call that state of the intellect insanity or not, the actions are often not regulated by reasonable motives. The existence of moral insanity, without any obvious intellectual derangement, can scarcely be doubted. How many murders have occurred in India, from apparently very unimportant causes, such as the excitement occasioned by the annoyance of soldiers being kept longer at drill than they deemed just or necessary, or employed at fatigue duty under a tropical sun.

Capital punishments must be either *retributive* or *exemplary*. How inadequate are our means of ascertaining the degree of moral guilt, in most cases,

so as to enable us to award a due retributive punishment in physical or mental suffering! "To acquire a complete knowledge of the guilt attached to an individual for an act of delinquency, it would be necessary to find out the secret springs that had led to the commission of each particular act—how much of the motive arose from the force of circumstances, acting momentarily on the mind, how much from a hardened disposition, and how much from mere weakness and mental imbecility." The vagaries of incipient and temporary insanity are easily mistaken for the outbreaks of reasoning insubordination; and after an offence has been committed, it is often impossible to obtain the requisite knowledge of the responsibility or of the motives of a delinquent, so as strictly to apportion punishment to guilt.

Exemplary punishments are perhaps not less difficult to award. To punish one man, for the purpose of deterring some other unknown person from the commission of crime, can scarcely be defended upon the common principles of justice, even if it were demonstrated that exemplary punishments are beneficial. But how rarely is it obvious that punishments inflicted for example's sake have possessed much of the deterring principle.

Flogging has been long the principal secondary punishment in the British army. In the early part of the last century, it was inflicted by means of rods, and by hired executioners; but that mode having fallen into disuse, the present system was adopted, namely, by drummer with the cat-of-nine-tails. During the rebellion in Scotland in 1745, the cat was much employed by the army, to extort evidence, as well as to punish soldiers. We learn by the Jacobite memoirs, that a sentry, who had been convicted of allowing a prisoner to escape, received 500 lashes with it.

The punishment of flogging has been employed and defended, apparently as if it were calculated to expiate or atone for crimes. Flagellation was no doubt approved by public opinion, so long as it was in accordance with the prevalent religious ideas. The church pointed out corporal inflictions as a means of salvation; and the repentant sinner believed, that by penance and

bodily suffering, he should recover peace of conscience.

Corporal inflictions were not then disgraceful, they being considered to possess an expiatory character. But this belief in the efficacy of flagellation and severe fasts has long disappeared. Public opinion in our day brands the punished criminal with an almost indelible disgrace; and perhaps the degrading character of corporal punishment is more sensibly felt in the army than in civil life, owing to the circumstance that it is exclusively inflicted upon private soldiers. Even those who defend the suitableness of flogging as a punishment, practically admit the degrading character of the infliction, by refusing to take a whipped offender into the public service: he is also liable to be refused employment in civil life. By this means, Prince Oscar inquires, "Is there not thus formed a class of *Pariahs*, or moral outlaws, who are obliged to consider themselves as being in a continued state of warfare with society?"

For a long time the cat-of-nine-tails has not been used in the British army except by the sentence of a court martial, and in the presence of a medical officer. At what particular date the formality of a court martial became essentially necessary, I have not learned. In a general order, which was issued in Canada on the 14th of November, 1759, it was announced that "any soldier that is found drunk will receive twenty lashes per day, until he owns where he got the liquor; and his allowance of rum will be stopped for six weeks."—(*Historical Journal of the Campaign in North America, by Captain Knor*, vol. ii. p. 205.)

No court martial seems to have been required, in carrying the above punishment into effect; and it is obvious that the cat was to be used as an instrument of torture, with the view of extracting evidence. Until 1836, there was no limitation to the extent of the sentence of a general court martial; "bounds were not set to show the maximum of punishment;" every thing, in this respect, was left to the discretion of the court. The following is the largest amount of punishment which I have known inflicted upon a man, for one and the same crime.

In 1813 or 1814, when a wing of the Bengal European regiment was stationed

in the island of Amboyna, three men belonging to the corps were tried by a court martial for marauding and ill-treating the natives. Each of the three men was sentenced to receive fifteen hundred lashes. A punishment parade being formed, and immediately after the reading of the sentence, one of the prisoners sprung forward, seized the drum-major's sword, and called upon the men in the ranks to come forward in his favour,—a request to which they did not respond. He was forthwith secured; and having been lashed to the triangles, he received the whole amount of his sentence, fifteen hundred lashes, well applied. The other two prisoners received each the same number, equally well inflicted. In the framing of laws rigor is necessary, but in executing them mercy is essentially required. The converse appears to have obtained in the above cases, the punishment having been more severe than was warranted by either former usage or express regulation.

The prisoner who was first punished was subsequently tried for his mutinous conduct in the square of the corps, and having been condemned to death, the sentence was inflicted by his being shot with musketry.

[To be continued.]

ACESIUS:

A SURVEY OF THE ETHICAL BEARINGS OF
MEDICINE.

By C. F. H. MARX, M.D. &c.

(For the *London Medical Gazette*.)

[Continued from p. 89.]

TO JAMES GREGORY.—

You never regretted the vast pains you took in Aberdeen, and Oxford, and Edinburgh, upon your classical education;—the root of all sustained effort is bitter, but the fruit is sweet.

That only which is perfect in its form and kind pleases the judicious, and outlives the times in which it was produced. Your elegant Latin has contributed not a little to your fame; and now, when your name is mentioned, you are commonly instanced as a model both of style and of matter.

Speech, it has been aptly said, is the man; and as a noble presence generally indicates a noble nature, so does an elegant style for the most part imply, that thought and study have been expended in equal measure on the matter.

But as in your day the medical author who could write with some little elegance, and make himself interesting to non-professional as well as professional persons, was one of the rarities—one of the white ravens or black swans—so it is at the present time. And it is even this state of things that leads me to pour out my complaint before you, with a faint hope that I may receive some comfort at your hands.

On the temple of the Delphic Apollo, as you are aware, stood the motto in golden letters: KNOW THYSELF,—as a kind of admonition to the approaching votary, that the Pythia dwelt within himself, in each man's own interior. The habit of questioning our proper genius, however, is becoming rarer and rarer: man appeals too little to himself; and our youth, by the distraction and multiplicity of their studies, seem scarcely ever to arrive at self-interrogation. The demands we make for knowledge are too manifold and too many; those for the mastery of what is known, and the right interpretation of what science imparts, are too few: a certain quantity of knowledge is required,—its quality is less thought of, indeed is apt to escape consideration altogether. The state machine, meantime, proceeds very regularly: the school and academy turn out ripe youths, approved by examination, and the university by and by hatches them into doctors; but they are still, and ever remain, mere tyros.

Every one runs after his object, and each is at length glad to be rid of competitors in the race. And then, by the pressure of the masses, it is becoming ever more difficult to give anything like special and sustained attention to any single subject: population increases; augmented facilities of communication bring the most distant boundaries of empires—the most distant empires, into contact; one discovery pushes aside another; and our steam presses, like ever active volcanoes, belch forth and scatter excitement on every hand.

He who is kept constantly in harness has enough to do with himself; care for his own existence suffers him to make no sacrifice for another.

In life this may be admitted; but whether it be well in science, and particularly in medical science, that is another question.

Much to be said, practitioners of medi-

cine, who above all men has to do with individuals, fix the whole power of his intellect and spirit upon the individual?

The problem entrusted to him both mentally and morally for solution or development appears to be this: not merely to recognize the tranquil spirit in the circle of eternal change, but to remain tranquil himself; and after having made the round once, to set himself to wrestle with details.

Even in the same measure as medicine expands—infinity, it may be said; as travels into new countries make us acquainted with additional articles of the *materia medica*; as chemistry from her furnace and alembic presents us with novel combinations influencing the bodily state; and as the microscope goes on enlarging more and more the smallest objects to the eager eyes of physiology and pathology,—in the same measure, I conceive, ought the true physician to strive after concentration and completeness in individual details.

Our schools have yet to make a beginning in this direction: the ideal in performance can only proceed from satisfaction with our daily occupation, from the longing gratified of simultaneous progress made in the real and the formal.

Who can bear witness better than you to the necessity and the reward of private industry, of occupation with the masters of our art, and the business of displaying the rightly apprehended in clear and simple terms?

The Dutch Hippocrates, who certainly cannot be reproached with the one-sidedness that is apt to attach to formal training, was in great measure self-taught*; his teachers were principally the ancients; and the singular amount of influence he obtained on contemporaries and posterity, he acquired mainly through the weight of a high and universal cultivation. When students, therefore, call out *panem et Circenses*—that the indispensable only be presented to them in their study-courses, and every thing be made easy as child's-play, the zealous teacher gains no dispensation in his labour.

* In the *Commentariolus de Vite cursu, propria Boerhaavii manu conscriptus* (vide Buntou's *Life of Boerhaave*, p. 207), we read as follows: "Est forsitan incredibile nullum de Nostro medicinæ cultum professore nisi vel. Breveintum vel. vicibus paulo ante fata."

It is not to be apprehended that the study of medicine will ever become a *torus medicatus*, a Graham's celestial bed; but it is certainly sought to be made attractive by books with the character of chrestomathias or school-collections: it has now its alphabetical cyclopædias, and treatises on anatomy and physiology, *materia medica* and surgery, that are ornamented with prints, like primers and A B C books for little children. Of all the components of the head, the eye alone is taken into consideration; where there is a picture there is no need of a thought.

At no time has the peripheral organ, the superficial, been so diligently laboured as at present. But when the external is treated of, when mere skin and covering are the subject, we are reminded of the ancient Myths, and recollect that, in the Argonautic expedition, miracles lent their aid; that the mast of the good ship Argo gave the bold adventurers a word of prophecy in season, and that Hercules lost his life by Dejanira's poisoned shirt.

True learning is becoming every day a greater and greater rarity in the medical man*; but as learning is still held to confer a title to consideration, so do we frequently encounter sham-learning—a certain mock familiarity with Hippocrates and Galen, and an ostentatious use of phrases picked up blindfold, and cast about at random†.

The study of grammar occasions so much misery at school, as you know, that the emancipated student seeks to be rid even of the recollection of his annoyances; and so it comes that errors, both in writing and in speaking the Latin language, soon obtrude themselves. Exceptions, it is true, occur occasionally among the members of our profession; but exceptions are still held proofs of the general rule. The learning of the dead languages is looked upon as an indispensable part of elementary education; and with our increased facilities for travel and intercourse, a knowledge of one or more of the living tongues of Europe is held a

necessary accomplishment. Many a one, however, who has the French and the German key at hand, has no familiarity with the *clavis Ciceroniana*, and many strange blunders are in consequence committed. The classics—I mean the books—are constantly taken from the gymnasium or academy to the university, and with the purpose of keeping them, like prize medals, to the last. In the hour of need the cry is: *surgite Triarii!* and, in the struggle, they find their way to the old-book-stall.

But even as little as high personal beauty is incompatible with courage, as little does a classical education stand in the way of practical accomplishment. Who, better than yourself, could satisfy us that those physicians on whose *index prohibitum* the classics had no place, have been those precisely who have been most distinguished by penetration of judgment and rectitude of conduct? It is but lately since I discovered that George Baker, the benefactor of Devonshire, the tracer of the cholic and paralysis, endemic there, to the presence of lead in the universal beverage of the county, cyder, and that derived from the use of leaden vessels, was an admirable Latinist.

Many medical writers exhibit what may be called a remarkable innocence in literature. They quote an author, for instance, without farther observation, and after the edition of him which they have at hand; they know Fontanelle, but not Fontenelle; they know no Hunter but one, nor any Monro but one; when Hamann is cited, they think of none other save him who was hanged: and on mention of Lichtenberg, they straightway conclude that the hermit of that name, whose interpretation of the pentagramma and other magical figures finds a place among the collected writings of Paracelsus, is the party intended.

The plastic arts, on the other hand, are commonly enough not regarded; there be medical men who know more of painters' schools than of painters' choice. And he who has no collection of medical portraits, still very probably possesses a fine engraving or two of some medical subject, such as L'Amour Médecin, or the Water-doctor of Gerrard Dow.

It were unfair to ask for too much

* S. C. Lucæ speaks briefly and well on this point in his oration: *Cur nostris temporibus multo parcius quam olim inter medicos juniores repantiur docti literisque satis imbuti?* Marburgi, 1820.

† The connoisseur exclaims with Aristophanes (*Nubes*, v. 960), at sight of the pretender: *Laugh! there comes a student again! The spit-box, quick!*

in such things. The artist has antiques, where much is wanting, for his studies; the physician has sick men, who lack much for his. Other casts than plaster casts of tumors and deformities might lead his fancy off in a wrong direction. The every-day practitioner must be familiar with the membranes—of the body—of every kind and description: whether or no he have ever seen and handled any other membrane of the kind discovered by Eumenes of Pergamus (parchment), than that on which his doctor's diploma is written, signifies not; his business is to order not Attic but Epson salt.

He who is fatigued with the toils of the day, at the present time, scarcely expects to find himself, like Arbutnot, seated in the company of a Swift and a Pope, descending on the fine arts, or drawing a portrait of Martinus Scriblerus;—but a novel from the circulating library is still held tolerable company; at all events it is not despised. It were, however, subject worthy of inquiry, whether the very greatest characters have not occasionally been beholden to such reading for their noblest conceptions.

Indulgence in the poetical faculty appears not to accord well with the multiplicity of detail in empirical science. Nietzsche, in his pathology, places the *furor poeticus* betwixt the *chorea sancti Viti* and the *furor uterinus*! How shall we wonder, then, that even the ancient physicians, whilst they willingly chewed Alexandrian raisins, which were without stones, so generally eschewed Alexandrine verses.

There have, indeed, been physicians who have been rather famous poets, such as Nicander of Colophon, Serenus Sammonicus, Aegedius Cabriolensis, Hieronymus Praecastorius*, Geo. Gottlob Richter, Albert Haller, Werlhof, Mark Akenside, and John Armstrong, and others who have interested themselves much for poets, as Garth, who, besides writing poetry himself, buried Dryden decently, and Currie who edited the works of Robert Burns—and Edward Jenner, too, let it not be forgotten, wrote verses. But with the best will in the world the Gradus ad Parnassum does not actually lead to

Parnassus: and though a lame Tyrtæus might inflame the Spartans, no practitioner of medicine will ever cure a cripple with his poetry.

Leaving poetry out of the question, then, not looking for any degree of skill in the art of "building the lofty rhyme" from the medical profession, I may still be allowed to complain that so many of its members write so carelessly; they might be sharply handled on the deficiencies of their prose style; and indeed impatience and spite almost tempt one at times to take it out of their skins,—Apollo stripped Maryas of his entirely for his indifferent writing,—were it not that as anatomists we know we should have to make somewhat severe inroads in the process upon the cutaneous nerves.

He who has even the most perfect processus styloideus in his skull, may, as you are well aware, have the most defective style of writing imaginable; there have not been wanting instances of such gentlemen, who, on this very ground, have given themselves out as genuine practical men. But against such pretensions I feel called upon to protest with the authority both of sacred and profane writers. The Gospel according to St. Luke is written in better Greek* than any of the other gospels; but the apostle was a physician. Such men as Celsus, Fernelius, Sydenham, Baglivi, Gaubius, Triller, William Hunter, and Cuvier, who took such pains with their language, can never be reached by the charge that they were word splitters and mere verbal critics.

Even as the cream shows the goodness of the milk, so do precision and elegance of expression indicate the parts of the writer. For style there is indeed no general rule or standard; it seems to vary with the prevailing spirit of the times, and differs as the period is one of tranquillity and indifference, or as it is marked by mental excitement and bustle; it is now argument and sequence, now daring and assumption, that takes the lead; at one time it is wit, at another it is seriousness that prevails; with leisure, men write at length, and are prosy; apt to become pressed for time, they are concise and

* Du Val (*Pictura linearis Sanctorum medicorum*, p. 4. Paris, 1613), says of him: *Divus Lucas scripsit Evangelium ornatissimo sermone, stylogue elegantiori, in gratiam Græcorum qui sermone venustate ac politiore literatura delectabantur.*

* The Bartholinus, in his *De Medicis Poetis* (p. 152, Hafnia, 1669), says of him: *Cum Veterum majestati certare valet.*

pointed. The elegant and the harmonious, however, are always in season.

And there let us admit the fact:—the wooden tablets covered with wax upon which the ancients were wont to write, have become, through Gutenberg's means, the tables of the law for mankind. In the brain there is a pen—a writing pen*, in sooth (*calamus scriptorius*); and the pen is now the prime feather in the wing that moves the world. And writing is wonderfully facilitated now in comparison with what it was formerly; and if not yet altogether free from danger, it is gradually becoming more and more so. By means of the pen machine, moreover, we have now a pen ready at a single snip, and with the steel pen we have nothing to fear from chips flying off into the eye in nibbing. And then we have glazed paper, which if it does not in any way spare the head, still saves the hand much inconvenience. Medical men, too, are now at liberty to spend all the more time on their periods, seeing that periodical distempers are cut short and cured with quinine.

Under these favourable circumstances I have a plan nearly ready—always with the proviso that you consent to accept the President's chair—for the foundation of a medical society for the cultivation of style. The society will of course, like other societies, propose prize questions from time to time, for which ample funds it is not doubted will accrue from the superfluous fees of physicians and surgeons during the first five (in London, ten) years of their lives as practitioners.

If you approve of the idea, perhaps you will be kind enough to select those you most approve of from among the following questions, and to fix a day for the inauguration of the society.

1. On the power to dispense with technical terms: a sermon.

2. On the untruths to patients that are admissible: a tale.

3. On the merit of unravelling tangled skeins: an ode.

4. On disputes and differences among medical men after the demise of the patient: a catechetical essay.

5. On the mutual confidence of medical practitioners: a dream.

6. On the agreements during and after consultations: table-talk.

7. On the friendships of medical men: a myth.

8. On the propagation of half true truths and untruths, and on innuendos: a medico-political enquiry.

9. On the acting—tragedy, comedy, and farce—of patients: a hymn.

10. On the physiognomy to be observed in presence of the patient: a sketch from nature.

11. On the selfishness of the sick: a satire.

12. On the cynicism of the medical practitioner: an elegy.

13. On undecieving medical men: a narrative.

14. On the complaints of practitioners at having no Sunday: a farce.

15. On the unexpected *rencontre* of two practitioners at the bed-side of the same patient: a physiological interlude.

16. On the struggle to become the family physician: an heroic poem.

17. On the mutual reconnoitings of colleagues: a novel.

18. On the dilemma of having neither sick nor sound to wait on: a popular ballad.

ANALYSES AND —ICES OF BOOKS.

“L'auteur se tue à allonger ce que le lecteur se tue à abrégé.”—D'ALEMBERT.

Introductory Address to the Students of University College, at the opening of the Winter Session in the Faculty of Medicine, 1844-45; containing Observations upon the effects likely to be produced by the Medical Reform Bill and the New Charter on the Surgical Profession and the Schools; Remarks on the expediency of combining Literary with Professional Pursuits; and Directions for the most advantageous Method of Studying Medicine and Surgery. By SAMUEL COOPER, Professor of Surgery in the same College, &c. Longman and Co.

EVERY thing from the pen of the author of “The Dictionary of Practical Surgery” is precious in our eyes. The compiler of such a work must needs be held a benefactor of mankind: he puts the best information on a subject of the highest importance to every man, within reach of all who have acquired the

* See my essay: *De Hierophilii celeberrimi medici vita, scriptis atque in Medicina meritis.* 4to. Götting. 1840, pp. 29, 30.

radiments of medical science; he presents his age with an epitome of the opinions and experience of all the mightiest spirits that have lived and expended themselves in that department of the healing art which requires manual interference.

Probably no single book that was ever written or compiled has exerted a more beneficial influence in its sphere than Mr. Cooper's Surgical Dictionary. Others have had medals struck, and pictures painted in their honour: our estimate of Samuel Cooper's deserts would not allow us to stop short of any proposition for less than a statue to him.

We should have felt it a duty, then, to notice any introductory discourse which the Professor of Surgery in University College saw fit to commit to the press; the time at which, and the circumstances under which, the present address is produced, made us even eager to peruse it; the table of contents on the title-page, it may be imagined, did not tend to lessen this natural desire.

Mr. Cooper commences his address by vindicating the 1st of October as the fittest season for entering on the business of the medical session. London stands almost, if not altogether, alone in this respect, however: and we are satisfied that the 1st of November, as in Scotland, and all over Germany, is the proper period. The courses delivered on the Continent are certainly not less complete than they are in London; yet the professors there find from the 1st of November to the 30th of April as good a six months as our London professors do the five months, or five months and a half, from the 1st of October to the middle or end of March.

"This session or term," says Mr. Cooper, "is remarkable as beginning at one of the most eventful periods ever known in the British medical world, over which the god Apollo, who of late may have been caught nodding, seems unlikely to retain much longer his usual influence, but must yield to the irresistible spirit of the times, and bend to the power of parliamentary enactments and royal charters." We are sorry to fancy that Apollo is to be discarded; Sir James Graham, we presume, has unseated him; but if he has been caught nodding, as Mr. Cooper insinuates, we have nothing to say in arrest of the judgment that awards his depo-

sition. Mr. Cooper then goes on to apologise for the introduction of medical politics, but thinks he will be excused for not passing them over altogether in silence. As the Medical Reform Bill is intended to govern the whole profession, its practitioners, its students, its several colleges, and its schools, he imagines it no wonder that some clauses and omissions in the bill should excite considerable discontent. The intended bill, however, he conceives, has "some wise enactments, which ought to save it from absolute and total condemnation."

"Some doubts," he proceeds, "I know, are entertained about the expediency of instituting a 'Council of Health and Medical Education;' and many sensible persons would prefer leaving the profession, as much as possible, to its own self-government, under which it is certain that medical science has attained in this country a degree of perfection not surpassed, probably not reached, in any other. In every attempt at innovation, this last fact must not be overlooked—it bears upon almost every question of medical reform; and, at all events, it dictates to the legislature the utmost caution in all its measures of interference with the profession. Whether the Council of Health and Medical Education, if it were established, would fulfil its intended high functions well and efficiently, would, of course, very materially depend on the talents, judgment, and the discretion, of the persons favoured with seats in it. If it were well constituted, I should expect that the profession and the public would be served by it in some respects, though not perhaps in every thing desired. By connecting the profession with the government, our notorious political weakness, as a body, would probably have a chance of being more or less obviated. To such an Institution we might look for more uniformity, more stability, and more consistency in the future regulations for medical schools, than has hitherto been manifested in the multiplicity of codes sent forth from time to time by an extraordinary number of councils and examining boards, without any harmonious co-operation—some modestly laying down the minimum as the fit principle for the curriculum; others, more bold, taking praise to

themselves for insisting on the maximum.

"The establishment of one supreme council for this most important duty, I should hope, would lead not only to the diminution, if not the discontinuance, of a petty, meddling, restless, and ever-changing system of legislation on professional education, but to the exercise of more wisdom in the recognition of hospitals and schools, than has been displayed of late years by collegiate and other authorities. If this superintending council were properly formed, I should entertain no fear myself of its adopting any measures likely to destroy the competition amongst the schools—an apprehension seriously expressed by one public writer of talent. In the endeavour to bring about some uniformity in these schools, it might direct the same subjects to be taught at all of them; it might even go so far as to order the same fees to be paid at all for them: but it would be entirely beyond its strength to cause medicine and surgery to be taught in all places with equal talent, efficiency, and success. In truth, the competition relates, not to the subjects to be taught, but to the manner of teaching them; and whatever this council may do, the schools will still laudably strive to emulate and excel one another in the value of the instruction delivered at them; because use on this must always mainly depend their own reputation and prosperity. Were the fees equalized in all the recognised schools, metropolitan and provincial, I imagine the fair and honourable competition, now referred to, would not be checked even by this absurd interference; but rather experience a fresh impulse, arising from the decline of small teaching establishments, which now live (if I may so express myself) principally upon their cheapness."

We are pleased to have the views of such a man as Mr. Cooper on this momentous subject. We have the pleasure of agreeing with him in all that he has said. We would only abate the word "absurd" in connection with the interference: interference was highly necessary, and the Council of Health and Education, *properly constituted*, it strikes us, as we have already had occasion to say, in securing uniformity of study and uniformity of fee in each country, will conduce immensely to the

efficiency of the educational establishments of each. Teachers at present cannot—dare not—insist on the attendance of their students; under the general regulations insisted on by the Council of Education they would have no difficulty in securing the presence of every young man who entered on every day throughout the session. And to the mass of common minds that engage in every study, in that of medicine among the rest, though the most extensive and difficult of all, the necessity of being in the way to acquire information is always of great importance. The better intellects are independent of teachers, but they are few; the poorer orders of minds are every way dependent on their instructors, and it is really of moment that they be compelled to take advantage of the opportunities that are afforded them: the community is even interested in their studies to this extent.

"As for some other parts of the Reform Bill," continues Mr. Cooper, "they seem to me fully to merit all the opposition with which they are threatened. The imposition of a tolerably heavy poll tax for registration; the still heavier payments to be made when a practitioner removes from the jurisdiction of one of the national medical colleges to that of another, an enactment directly at variance with the long-desired equal validity of their diplomas in every part of Her Majesty's dominions; and lastly, the omission of an efficient clause to protect the regular practitioner, *i. e.* to prevent unexamined persons from practising and assuming the title of surgeon; are, according to my view, amongst the most objectionable features of the Bill as it now stands. Indeed, if it had not some other clauses of fairer promise, I should have been disposed to suspect, that those philosophers, who concocted it, had considered us in their experiments (as Burke would have said) 'no more than as mice in an air-pump, or in a recipient of mephitic gas.'"

This is quite unequivocal, and Mr. Cooper's words are but the echo of the voice of the entire profession.

Quitting "The Bill," Mr. Cooper approaches another knotty point—"The Charter recently granted by Her Majesty to the Royal College of Surgeons of England, which will be scarcely less important in its effects

upon the surgical community of this kingdom. Practitioners and students in surgery generally—every medical school, and every teacher—all who are, or intend to become, either regular surgeons or general practitioners—will be more or less affected by it. The establishment of the higher grade of the Fellowship, only now to be obtained on special examination by candidates who are at least twenty-five years of age, and have devoted six years to the study of their profession at specified schools or hospitals, is quite a new state of things. Nor is this all; for, in addition to this lengthened professional study, a superior preliminary education is insisted upon, embracing a competent knowledge of the Greek, Latin, and French Languages, and the elements of mathematics, to be certified by special examiners. Some relaxation of this part of the by-laws is allowed for those who are now members of the College, after they have attained a certain standing; but all future members, and others who aspire to the Fellowship direct, without having been previously members, must comply with these regulations.

"The candidate for the Fellowship must have been engaged for six years in the acquirement of professional knowledge in recognised hospitals, or schools of surgery and medicine within the United Kingdom, or in foreign countries; and three of such years at least must have been passed in one or more of such hospitals or schools in London. The candidate is to have attended the surgical practice of a recognised hospital or hospitals during four years, and the medical practice for one year.

"He must have studied anatomy and physiology during three winter sessions, and have attended lectures on the Theory and Practice of Medicine, on Clinical Medicine, on the Theory and Practice of Surgery, and on Clinical Surgery, during two sessions.

"He is also required to have attended one course on each of the following subjects; viz. Chemistry, Materia Medica, Midwifery, Medical Jurisprudence, and Comparative Anatomy.

"He is to have served the office of house-surgeon or dresser in a recognised hospital in the United Kingdom; and he is to present for examination clinical reports, with observations, of

six or more surgical cases, taken by himself at a recognised hospital, with certificates of their authenticity and genuineness.

"Candidates who have taken the degree of B.A. at an English university are not required to undergo an examination in languages and mathematics; and the period of their professional study is reduced to five years.

"Gentlemen, all these matters ought to be correctly understood by you, because the plan necessary to be pursued, in order to obtain the Fellowship, will be materially different, in several respects, from what you would have to follow for the ordinary diploma. If you mean to try for the Fellowship in the first instance, and at the earliest legitimate age, your time of professional study will be from the age of nineteen to that of twenty-five; but if you mean to go up with the degree of B.A., the age of twenty will be early enough for you to enter at a medical school. If you intend to qualify for the ordinary diploma, which can be obtained at the age of twenty-one, four years' professional study at a recognised hospital and school is the condition fixed upon by the regulations to render you admissible as a candidate.

"Whatever may be the defects of the new charter, and however well founded the disappointment, caused by the impossibility of doing full justice to all in the late nominations to the Fellowship, it is my sincere belief that, inasmuch as this charter enforces a higher standard of education, both general and professional, as an essential step to the superior grade, it will not only promote the advancement of scientific and practical surgery, but confer rank, influence, honour, and dignity, on the surgical profession."

We take the opportunity of Mr. Cooper's exposition to make known to our younger friends what will be required of them if they would aspire to the Fellowship of the Royal College of Surgeons of England. We are sorry to differ with Mr. Cooper upon this subject. The Fellows are all intended by the concoctors of the Bill and Charter to be men of means and position in society; they can never form more than a minority—a small minority—of the profession, and their practice will all lie among the wealthy and the great. But we are of opinion that the wealthier portion

of society will always find itself provided with the Doctor Sangrado of the profession, irrespective of legislative enactment; we do not think it in any way requisite to legislate for the aristocracy of the country, in the matter of highly educated medical men: these they will always be able to command without any special provision made by act of parliament; it is for the *Gil Blas* of the profession, and for his patients, the commonalty, that we are solicitous. And this point we think Mr. Cooper overlooks entirely in his commentary on the Charter—it was not his cue to do otherwise; Mr. Cooper is a member of the Council of the Royal College of Surgeons, that has separated itself from its constituency—its members—and proposes to stand alone and isolated, or, as it has been said, to exist through the rotten support of partiality and favoritism, setting at defiance every principle of right, to say nothing of fair play, which is only right of another kind, and singularly dear to the nature of Englishmen.

Mr. Cooper recommends the young men he is addressing to strive for the highest place. "Your first ambition," he says, "should be to belong to the enlightened class in the profession, who (to use the words of Dugald Stewart) 'are distinguished from the half-informed multitude who follow the medical trade.' Endeavour to be courted by society, not for your professional skill alone, but for your learning, intelligence, and general information, combined with strict moral integrity, and all those delicacies of thought and conduct which are essential to the character of gentlemen." Surely this is right, but as we said, the Fellowship is among the *reserved* seats. The Bill, and the Charter, which is but a rider on the Bill, do not provide Fellows as the representatives of the medical profession, but Licentiates in medicine and surgery, with a minimum of education; more than this, the authors of these measures have very obviously contemplated leaving the community to the care of wholly uneducated persons—to the care of chemists and druggists, to say nothing of empirics and quacksalvers of every style and denomination.

But we have already far exceeded our limits in this notice of a pamphlet of but some thirty-four pages. Its

subject, and the distinguished member of the profession who is its author, must be our apology. We have only quoted the graver matters: the Discourse deserves to be read; its quiet humour, and its excellent sense combined, give it a rare charm, and add a zest that makes reading a real pleasure.

MEDICAL GAZETTE.

Friday, October 25, 1844.

"Licet omnibus, licet etiam mihi, dignitatem
Artis Medice lueri; potestas modo veniendi in
publicum sit, dicendi periculum non recuso."
CICERO

THE EDUCATIONAL PROPOSALS OF THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.

WHEN we begin to feel aweary in the course we have been pursuing ourselves, we have a shrewd suspicion that those who accompany us are also beginning to be fatigued. We have set ourselves the task of going through the Medical Bill, clause by clause; and we mean to accomplish the labour;—we beg for one week's relaxation, both for our own and our kind readers' sake.

We are often indebted to our friends and correspondents for a hint, which serves us by way of text for our weekly essay. The following letter came some short time ago into our hands, and we have to apologise to its writer for not having sooner made the use of it he doubtless intended we should:—

To the Editor of the Medical Gazette.

SIR,

I have just now quitted the perusal of one of the numbers of your last volume, which contains a very learned article "*On the Army Surgeon.*" I most cordially agree with the author of that article, Dr. Hull, that "some distinct history is wanted of army surgeons;" but, in connection with an account of the most distinguished army surgeons, and their contributions to science, it were very desirable that we should have a brief history of the rise and progress of the medical branch of

the British army. I lately observed a letter in the Naval and Military Gazette, recommending a work of this kind; and as there are 500 well-informed medical officers on full-pay, it is difficult to imagine why it has not been undertaken long ago. It does not appear that any specific general code of military hygiene has ever been promulgated for the guidance of military and medical officers in the British army. Why are we so far behind other countries in this respect? Dr. Hull observes, that "the Director-General has done wonders to secure the comfort of medical officers, to maintain their dignity, to secure their efficiency, and to advance their science." What has been the result of this distinguished patronage? In what respect, and to what extent, has the science of medicine been thereby promoted? The public have no means of obtaining information on these subjects but through the periodical press.—I am, sir,

Your obedient servant,

A HUMBLE INQUIRER.

Peterhead.

We think we can answer one or two of the important points in our correspondent's letter. Why we have no history of our army medical men, may probably be because biographical and historical writing of any kind is at a discount in England at this time; it is at a double discount in connection with medicine and medical men, seeing that literary tastes and talents, instead of proving of service to the physician or surgeon of Great Britain, rather tend to damage him in public estimation. This fact is greatly to be regretted; it is impossible to calculate the amount of good that is *not* done, merely through want of the habit of writing, and the indisposition to write which a conscious want of facility in the operation engenders. He who fills an office in any of our great establishments for the treatment of disease, ought to hold himself responsible to the public and his brethren for making the utmost of his opportunities; the physician, the surgeon, to a great hospital, is not

there merely for his own special aggrandizement; he is bound to impart, by teaching and writing, what he meets with that he knows must be useful and interesting to the profession of medicine at large. All cannot have such opportunity; but all may be made in a signal measure to share in its advantages.

Our excellent friend Dr. Marx, in his letter to Dr. Gregory, the author of the far-famed *Conspectus Medicinæ Theoreticæ*, published in this day's GAZETTE, adverts well and opportunely to the advantages of literary tastes and habits, and shews that some of the very first masters in our art were men who were even scrupulously nice in their diction. Cuvier was an elegant scholar, and one of the best writers of his country; yet who shall say that he was not a practical man? William Hunter says expressly, that considerable writers have for the most part been considerable practitioners also; and he was himself one of the most brilliant examples of the finished scholar and man of letters attaining to the highest position as the practical physician. Nay, our own persuasion is, that no man without the habits of attention and observation and arrangement, which the practice of committing his thoughts to paper alone calls forth and cultivates, can ever attain to anything more than a merely secondary place in his profession. He may, by force of family connection and influence, be furnished with a brilliant place as physician or surgeon to an hospital; he may, even, by dint of what is called tact, or as the French have it, *savoir faire*, acquire name and fame as a practitioner; but his reputation does not extend beyond his own circle, or the city he inhabits; he is no member of the republic of letters; he has never impeded the wing of time with a new feather; he has probably done nothing more during life than feather his own

nest somewhat warmly. It frequently happens, when the name of such a man is mentioned to a distinguished foreigner, that the distinguished foreigner has never heard of him: had the distinguished foreigner lived in London, or wherever else the successful man was domiciled, he would not have been so ignorant. He who out of the store of ample, of unusual, opportunities, contributes nothing to the common stock of information, cannot be held to have lived to purpose, though he may have founded a family and made a handsome fortune.

Mr. Cooper, in his Discourse, noticed in this day's GAZETTE, speaks of the accomplishments which the Council of the College of Surgeons mean to require in the future candidate for its Fellowship. The object aimed at is evidently to get classical scholars for surgeons as well as for physicians. We are far, very far from objecting to this; we shall be delighted to see a larger infusion of the *literæ humaniores* into the minds of surgeons. From henceforth we may trust that they among them who fill the principal places will be better disposed than their predecessors, or than they themselves have yet been, to estimate general information and learning in others. That they will not, as in times past they have frequently done, check the aspirations, and even injure the prospects, of men unfavoured by private fortune or family influence, who are struggling manfully with adverse circumstances, by cold words to the effect that, "they were mere men of letters," that "they were not practical men," and the like. Letters, it is certain, will not give experience; but experience, we insist on it, is most powerfully and most effectually aided by letters. The dreamer may be well lodged in the body of him who is no student;—the speculator in science at the present day, indeed, is always the

indifferently informed man; and the practical man may be, and often is, the core, the life, the soul of the devoted student.

With the encouragement of liberal acquirement on the part of the Council of the Royal College of Surgeons, we have better hopes of the profession, both in reference to future members, and to present consideration with the public of men who are really informed beyond the procedure in given circumstances that is adopted at St. Bartholomew's, or St. George's, or the Borough Hospitals, of men who prefer reading and writing, and the quiet of their study, to whist and idle assemblies. The time may come, must come, is come, if the Council of the Royal College of Surgeons mean anything of good by their enactments, when these men will not be twitted with their tastes and their accomplishments, by the so-called practical men, the gossips of the hospital board-room, through the earlier years of their professional life; by and by the inefficient because ill-informed occupants of the principal offices in the establishment. With the habits and talents which the more liberal course of study now to be required of the student in surgery will develope, we hope that our correspondent, or another, his representative in times to come, will be furnished forthwith with a history, not only of British military medical men, but of British military surgery. That this is still to write cannot be laid to the charge of the Director-General of the Army Medical Department. He has made as much as could be made of the materials with which he has had to work; and seeing that his ranks have mostly been recruited with levies of raw youths, often little more than 18 or 19 years of age, and, of course, defectively educated both generally and professionally, it is a wonder that he has been able to do

so much as he has unquestionably accomplished. The Council of the Royal College of Surgeons, in their educational enactments, seem disposed to sow the seed that will by and by bring forth such good fruit as our correspondent requires, among much besides that we doubt not will be found excellent.

MOVEMENT IN THE PROFESSION.

ON Tuesday last a large meeting of the general practitioners of Bradford took place, for the purpose of considering the New Medical Bill: Mr. Beaumont in the chair. "Hailing with satisfaction the introduction of a bill into parliament for the better regulation of medical practice, which the meeting was of opinion contained provisions calculated to raise the position of the medical profession, and to secure a higher and more uniform standard of qualification, it still maintained that the Apothecaries' Act of 1815, though it contained much that is objectionable in principle, yet that its unconditional repeal would be attended with evil to the medical profession and to the public, by removing all restrictions on unqualified and ignorant persons: having, however, experienced the reluctance and also incapacity of the Worshipful Company of Apothecaries, to check illegal practitioners, it is the hope of this meeting that some more stringent and summary measure be introduced into the bill, for the better protection of the public as well as the profession."

A committee was then formed for the purpose of holding communication with the borough members, &c. The meeting was most harmonious: all the resolutions were passed unanimously.

At CHESTER on the 10th inst., a meeting of the medical men of that town and neighbourhood was held at the infirmary Dr. Thackeray in the chair. The business of this meeting may be summed up in this single resolution.

1.—It is the opinion of this meeting, that the present state of the medical profession requires numerous and speedy amendments; and whilst we cordially admit that many of the proposals made by Sir J. Graham would materially effect desirable and extensive improvements, still we conceive that there should be appended to the bill a

decisive protecting clause, to punish the unqualified, and to protect the public from the practices of untaught and unskilful pretenders.

A petition in conformity with the views here declared was then agreed upon: a committee was appointed to keep a sharp look out upon Sir James Graham, to confer with the county members, &c., and the meeting separated.

At SHEFFIELD a numerous meeting of the members of the profession was held in the Cutler's Hall on the 16th inst.: Dr. Thompson in the chair. Resolutions well drawn and carefully worded, were adopted, to the effect that whilst the meeting viewed with satisfaction the attempt now made to put an end to the dissensions unfortunately for some time back existing in medical government; the endeavour to connect so important a branch of the social community of this country as its practitioners of medicine with the state; the registration of medical men, and that clause of the bill by which degrees in medicine conferred without residence and without examination are not recognized, yet that in the opinion of the meeting, certain provisions of the intended bill were decidedly objectionable, especially that which removed all restriction on the practice of physic and surgery.—But the sense of this meeting is well shown in the petition which they agreed upon, and which is as follows:

"That your petitioners witness with great satisfaction the introduction of a bill intituled 'A Bill for the better regulation of Medical Practice throughout the United Kingdom,' which by its provisions will, in the humble opinion of your petitioners, conduce to the dignity and interest of the medical profession by connecting it with the state, by favouring an efficient registration of all legally qualified members, and by not recognizing degrees in medicine conferred without residence and without examination.

"That your petitioners deeply regret that the intended bill does not afford that protection from the irregular practices of unlicensed persons to which all legally qualified practitioners feel they are fully entitled, and humbly pray that your Honourable House would be pleased to enact some clause by which

such persons shall be more summarily dealt with, and such practices effectually prevented."

At a meeting of the profession held at SHREWSBURY, resolutions were passed expressive of satisfaction that the government had at length interfered in the subject of medical reform; that whilst several of the provisions of the bill were hailed with satisfaction, yet that it seems imperative, should the act of 1815 be repealed, that some other enactment should be substituted for it, for the protection of the public and the profession against irregular practitioners. A petition to the houses of parliament was then agreed on, and arrangements made for deputations to wait on the county and borough members.

At COLCHESTER, a large meeting took place on the 15th inst.: Alderman Partridge in the chair. The worthy alderman went further than any whose words we have yet seen reported in connection with the bill. Far from giving utterance to either doubt or dissent, Alderman Partridge expresses his concurrence generally with the provision of Sir James's bill, which, indeed, as a first attempt at legislation, he thinks *approaches very near perfection!* Many men, many minds: Sir James Graham must be satisfied of one thing at least by this time, that he will never get the medical body to be of one opinion in regard to any measure he may propound. The meeting over which the alderman presided, however, seemed to be every thing but of his way of thinking: in proposing the 1st resolution, Dr. Williams characterized the Council of Health and Education as a body "to be invested with extravagant and irresponsible authority," and as involving "monstrous inconsistency in its formation;" whilst the resolution itself, which was carried *unanimously*, contains these words: that the bill, as brought forward by Sir James Graham, "is made inadequate to the purposes proposed."—It is inadequate to the purposes which Dr. Williams and the Colchester meeting propose, we make no doubt; but we are not so sure of its inadequacy to effect the objects which its framers had in view.

The second resolution most strongly protests against the repeal of the act of

1815, unless an equivalent protection be substituted, and an uniform elevated standard of professional education be enforced;" nevertheless, Dr. Chambers, in seconding this resolution, was inclined to view the bill as a whole favourably; the introduction of a clause enforcing a penalty for irregular and incompetent practice, recoverable by some inexpensive process, would bring the measure as near to perfection as could be expected. Other speakers took less favourable views of the tendency of the bill; but the whole meeting appears to have been conducted in very good taste, and with a perfectly good understanding. A petition was agreed on, in which, in spite of the smooth words of Alderman Partridge and Dr. Chambers, the bill for the better regulation of the medical profession is boldly stated "to be inadequate to such an end" it is, farther, "viewed with dissatisfaction and disappointment, because while professing to protect the public health and the medical profession, its tendency is believed to be grievously destructive of both, since it offers direct encouragement to empiricism with its enormous and incalculable evils, and tends to degrade the educated and legalized practitioner, and to retard and discourage medical science;" in fine, after objecting to the repeal of the act of 1815, without some more stringent substitute for it, and to the Council of Health as "exceedingly defective and objectionable," the petitioners "pray respectfully and earnestly that the above named bill may not pass into a law."—Here, then, are men evidently of peaceable disposition and good feeling, blowing hot and cold, saying "aye" in one breath, and "no" in another, and altogether shewing a want of consistency and independence which we often regret in our profession. We fear that there is something at the bottom of the "lip honour" and support of the one party, and of the more consequent, and therefore powerful opposition of the other party, which does not appear. In such a meeting as that of Colchester, we see, in fact, the spirit that dictated the bill arranged on the one side, and that which now opposes it so lustily marshalled on the other. The doctors may talk, and as Sam Slick, would say, use "soft sawder" to the authorities and their bill, to any extent they please, but

resolutions damnatory of all they had been saying, carried *nem. con.* too, they themselves, therefore, gainsaying all they had just uttered, present our brethren to us in a light which is very far from favourable, whether we look on them on the side of intellect or of character.

We have notices of other meetings which are purposed, and of which we shall speak in due season, particularly one to be held at Northampton, and another at Chichester, both on the 31st instant.

SYDENHAM SOCIETY.

[WE have the following from a learned and esteemed contributor.—ED. GAZ.]

OUR opinion of the new Latin edition of Sydenham has been already expressed; but as we understand that the Sydenham Society proposes to publish also an English translation of his Works, perhaps we may be excused if we venture to give a few hints on the mode in which we think that this and other similar versions should be executed. To enter upon the subject of Translation generally would be an interesting, and not wholly unprofitable employment; but still we must not allow ourselves to forget that ours is a *medical*, and not a *philological* journal, and therefore we must be content to confine ourselves to the subject now before us. Our remarks will have special reference to Sydenham; but, as many of them will apply equally to most of the other older authors, perhaps they may be useful to some of those gentlemen who are thinking of translating their works for the Society. We had intended to say something on the text that should be used, the amount and character of the notes that should be given, and some other similar matters; but these we shall reserve for some future occasion (if any should occur), and merely at present offer some suggestions on the *style and language* in which we think these old writers should be brought before the English public.

Of Sydenham's Works there are two translations; one by Dr. Pechey, which was first published in 1693, and of which the eleventh edition appeared in 1740; and the other by Dr. Swan, which first appeared in 1742, reached the fourth edition in 1763, and was considered so good by Dr. Wallis, that

he republished it in 1788, with a very few verbal alterations. The question naturally arises, which of these two translations should be taken as the basis of the new one? and probably most of our readers will at once be inclined to prefer the later, on the presumption that a new translation would not have been made if it had not been wanted, and would not have been published if it had not been better than the old one. Such, we confess, was at first our own idea, but we remember to have learned at school that *Ἀτ' δευτέρα πῶς φροντιδὲς σοφώτεραι* (Eurip. *Hippol.* v. 438), or, in plain English, that "second thoughts are best;" and, accordingly, we have since seen reason to alter our opinion. Apparently Drs. Swan and Wallis aimed at bringing Sydenham's Works up to the standard of medical science in the last century, and also at modernising his old-fashioned style. These two objects they endeavoured to effect, first, by adding a quantity of "notes, corrective and explanatory, from the most eminent medical writers, adapting the whole to the present improved state of physic;" and, secondly, by omitting various epithets, proverbial phrases, and classical quotations and allusions, which were commonly used in the seventeenth century, but had grown out of fashion in the eighteenth. We are inclined to think that they failed in both these attempts. With respect to the scientific part of their task, we should very much doubt whether even Dr. Wallis's "corrective and explanatory notes from the most eminent medical writers" could have succeeded in adapting Sydenham's Works to "the improved state of physic" in the last quarter of the eighteenth century. On the literary and philological question we can speak with still more confidence. We forget at the moment who it was that spoke of a bad translation as having "*done* his author *out* of Latin, without having *done* him *into* English;" but this expression seems exactly applicable to the labours of Drs. Swan and Wallis. By means of the omissions and alterations before noticed, and also by using the common literary words and expressions of their age, they have effectually *done* Sydenham's Works *out* of the style and language of the century in which he lived, but they have unavoidably left so

many peculiarities still remaining, that they have not been so successful in *doing* his writings *into* that of their own. So that altogether their work is a perfect anomaly; it is too modern to be read as a work of the seventeenth century, and too old-fashioned to pass for one of the eighteenth; and therefore cannot be read with satisfaction in either point of view. If this was the case in the last century, much more would it be so in the present; and therefore we are inclined to think that the translator should abandon the ambitious aim of making Sydenham write as if he had lived in the nineteenth century (which, indeed, could only be done by a person of kindred mind with Sydenham himself), and content himself with presenting his work to the public as nearly as possible in the state in which Sydenham would have written it if he had used his native language. If this be admitted, the question which we proposed above suggests at once its own answer. Pechey's translation was published so soon after Sydenham's death, that it may be considered as a contemporary work; and though he occasionally takes more liberties with his author than we hope the new translator will allow himself, yet the omissions and alterations are of a different kind from those which we find in Swan and Wallis, and are apparently rather the result of carelessness than design. We think, then, that Pechey's translation (however quaint and old-fashioned it may appear to those who are not familiar with the style of the writers of the seventeenth century) should be taken as the basis of the new one, or rather that the new one should be merely a revision of the old; and if this be done carefully, we are inclined to think that the editor will find that the labour of revision will not be much less than would have been that of executing an entirely new translation of his own.

We had thought of confining ourselves to the style of the text, but we must be allowed to add the following remark as a short corollary to what we have said above on the futility of the attempt to bring Sydenham's writings up to the standard of modern science; whence it follows that the notes, instead of attempting to correct errors of the text, or to supply its deficiencies, should be simply explanatory and illustrative—not that we do not think

generally best performed in the fewest words.

PHYSICAL SOCIETY OF GUY'S HOSPITAL.

T. CALLAWAY, Esq. in the Chair.

ON Saturday the 19th, the second meeting of the session took place; the President congratulated the society on the numerous attendance, and apologized for the non-appearance of Dr. Ashwell's paper as promised last meeting. An interesting case of foreign body in the throat, was read by Mr. Cole, dresser of the hospital. A child, aged 1½ years, while playing with a large piece of plum stone, placed it in its mouth, and was suddenly seized with the most alarming symptoms of asphyxia. By the advice of a neighbouring practitioner the child was sent to Guy's Hospital, which was fortunately close to the residence of its parents. The dresser immediately passed his finger over the tongue into the larynx, and felt the foreign body, but being unable to dislodge it by this means, he directed the child to be held up by its heels, and in this mode, with the aid of a probe passed by the side of the finger, he succeeded in removing it. The child was now taken by two assistants, who practised artificial respiration by compressing the ribs, and eventually restored the natural breathing; the child has since done well.

A discussion ensued, in which several cases of foreign bodies entering the larynx, and being subsequently expelled by the natural powers, or by the operation of opening the trachea on the one hand, or proving fatal immediately by asphyxia, or remotely by inducing phthisis on the other, were related or alluded to by different speakers, one in particular by Dr. Bossy, where an ear of hordeum prateuses was accidentally drawn in by a child between 3 and 4 years of age, and subsequently ejected impacted in mucus. It was somewhat curious, he observed, that the father of this child, a nobleman, became the victim of phthisis from accidentally swallowing a single grain of barley, which was found on inspection after death within the pulmonary excavation. The length of time that respiration could be suspended in cases of submersion in the adult, and of the fœtus, in footling births, and after the death of the mother, so as to ascertain the prospect of recovery in still births, and how long after the mother's death there was any hopes of saving the child by the Cæsarean operation, as well as the best modes of treatment in cases of threatened asphyxia, were simultaneously and rather actively discussed till the hour of adjournment arrived when the

author, and a paper on Hooping Cough by Mr. Streeter was announced from the Chair for that day fortnight.

CHEMISTS AND DRUGGISTS.

To the Editor of the Medical Gazette.

SIR,

I PERCEIVE that at many of the meetings held for the purpose of considering Sir James Graham's Medical Bill, the Apothecaries' Company have been lauded, and I must allow deservedly, for raising up a highly qualified body of medical practitioners—a duty which appertained more properly to the higher bodies in the profession, viz. the two Colleges of Physicians and Surgeons, but which was most egregiously neglected by them. At the same time that we are bound in honour to acknowledge that to them is owing the increased acquirements and efficiency of the *general practitioner*, it will be impossible to deny that they have entirely forgotten and neglected the duty *actually* devolved upon them by the Act of 1815, by the legislature, viz. that of providing *apothecaries*, whose duty was, as specified in that Act, the careful and accurate dispensing of physicians' prescriptions with pure and unadulterated drugs, &c. Now the slightest inquiry will shew, that the great bulk of their licentiates utterly repudiate the idea of dispensing a prescription for any one whom they are not attending in the capacity of a general practitioner. And as respects dispensing assistants, to secure whose efficiency County Boards of Examiners were provided by clause 18, it is no uncommon thing for the boy who commences by carrying out the medicines being gradually advanced to the important post of compounder of prescriptions, where he continues till he is old enough to be his own master, when he commences business for himself as one of that favoured body so specially protected by clause 28, viz. chemists and druggists, to whom the major part of prescriptions must unavoidably be sent. Under these circumstances, I, for one, cannot but feel, that unless the Apothecaries' Company are prepared not only to resume their original duty, but also to apply to Parliament for additional power, enabling them entirely to control the compounding and retail sale of drugs and chemicals, the Act of 1815 ought to be repealed, and some other body be appointed by the legislature for that object.

The judicious prescription of the physician, surgeon, or general practitioner, will avail little, if pure and unadulterated articles are not used in the composition of it; and, whilst any one may engage in the business of a chemist and druggist, there is no guarantee that such, and such only, will be used. As regards the *sale* of drugs, why it is notorious that any one who chooses to combine

the sale of opium and arsenic with that of sugar and starch, may do so, the law assuming that every one is capable of protecting himself! Mr. Taylor, in his able report on Toxicology, states that more than a hundred lives are yearly sacrificed in England and Wales, by the unrestricted manner in which arsenic is sold. Surely it is the duty of the legislature to protect individuals against those accidents which are liable to occur through the ignorance or criminal neglect of others. This question, which so deeply concerns the public at large, fails to excite that continued attention which it ought to do, because it generally comes before them in single instances, when the coroner's inquisition, or a trial for manslaughter, takes place. It therefore becomes the duty of the medical profession, who are perfectly acquainted with the magnitude of the evil, to press upon the attention of the legislature the immediate necessity for an effectual protection against this sacrifice of life.

Though the chemist and druggist is at present out of the pale of the profession, and however much we may be disposed to look down upon his position, it is impossible to deny his connection with the present practice of medicine, and that to a very important extent. What avails the beautiful idea in the mind of the sculptor, if he cannot obtain the block of marble to embody it? Believing the present to be a favourable opportunity for the consolidating and arranging of all medical questions, I am induced to solicit your attention, and that of your numerous readers, to a branch of the subject which, I regret to think, too many consider unworthy their consideration, but which, if left to itself, will be a source of discord to the profession, and of injury to the public.

I am, sir,

Your obedient servant,

GEORGE SOULBY.

Dover, Oct. 7, 1844.

SOCIETY FOR THE RELIEF OF THE WIDOWS AND ORPHANS OF MEDICAL MEN IN LONDON AND ITS VICINITY.

A HALF-YEARLY general Court of this useful and excellent Society is advertised to be held next Wednesday evening, in the Gray's Inn Coffee House, Holborn.

The new President, recommended by the Court of Directors, in the room of the late Sir Henry Hallford, is Sir Charles M. Clarke; and, doubtless, Dr. Latham will be chosen to fill the office of Vice-President, which will thus be vacated. Mr. Hunter, of Mincing Lane, has expressed his readiness to undertake the office of acting Treasurer, in place of Mr. Bacot, who retires, after having for many years ably discharged the duties of that important trust.

WILSON & OGILBY, 57, Skinner Street, London.

LECTURES
ON THE
NATURE AND TREATMENT OF
DEFORMITIES,

*Delivered at the Bloomsbury Square
Institution.*

By R. W. TAMPLIN, F.R.C.S.E.
Surgeon to the Institution.

TREATMENT OF TALIPES VALGUS.

GENTLEMEN,—At our last meeting I pointed out to you the character of talipes valgus; that it was both congenital and non-congenital; that it consisted in a sinking of the bones forming the arch of the foot, from a yielding of the ligaments and of the plantar fascia, together with the muscles of the sole. That both the longitudinal and transverse arches were gone, and that a perfectly flat position of the bones of the tarsus was the result, combined with an eversion of the anterior portion of the foot; this effect arising from the greater amount of muscular power being in the middle and outside of the foot. That the internal lateral ligament is elongated, as well as the calcaneo-scaphoid ligament. That the muscles in their action have a tendency to increase the malposition, in consequence of the firmness of the fulcrum upon which they act being to a great extent destroyed; that this applies to the muscles in the sole of the foot, as well as to those passing over and through it; that it was unaccompanied with paralysis, and appeared to me to originate primarily in the yielding of the passive connecting media between the tarsus and metatarsus. That in the congenital cases, I regarded it as the result of position maintained during the embryotic existence up to the period of birth. That non-congenital cases are met with in persons of all ages, and that a general weakened constitutional condition is a predisposing cause; although the deformity was often attributed to

much standing in one position, or to the effect of carrying heavy burdens. That in the most severe cases the motion of the joint is altogether interrupted, from the astragalus falling on its inner side and lying in an oblique lateral position in the articular cavity; the outer articular surface pressing on the articular surface of the fibula; the inner on the corresponding articular surface of the tibia, and to this I attribute the pain experienced by the patient in walking: that at times the patient would almost appear to touch the ground with the inner ankle; that at all times great lameness and difficulty in walking are the result, and that occasionally those suffering from this deformity had been obliged to abandon their ordinary occupation. That the muscles generally found contracted were the peronei and extensor communis digitorum, the peroneus longus et brevis everting the foot; the peroneus tertius and extensor communis raising the outer edge thereof. That the method I had adopted of dividing the peroneus longus and brevis consisted in passing a sharp-pointed knife between the tendons and the bone, with the flat surface of the knife to the tendons; afterwards turning the knife half round, depressing the handle, and with the sharp edge towards the tendons dividing them. That in dividing the common extensor you would pass the knife on the inner side beneath the whole at the same time, and divide them by one operation. That after the punctures were healed you would commence the extension and adduction, which being accomplished you would proceed with the flexion; and as soon as the foot was brought into position the arch of the foot should be supported with a cork sole with a support reaching from below the knee. That it was absolutely necessary to maintain the position uninterruptedly, night and day, for a longer or shorter period, until the foot could support the weight of the body without a return to the malposition unaided by any artificial support. That if the patient be allowed to use his foot previously

to attaining this, a return of the deformity would be the inevitable result. I then drew your attention to the two kinds of deformities which were considered as a compound of those previously described, namely, that of contraction of the gastrocnemius muscle combined with either eversion or inversion of the foot, and which I designated by the respective terms of talipes equino-varus, and talipes equino-valgus. That I considered it an unnecessary multiplication of names, especially as regards talipes equino-varus, as both in varus and talipes equino varus the causes are the same—the muscles contracted the same, the treatment the same, differing only in degree. That in talipes equino valgus there is, however, a contraction of the gastrocnemius which I did not consider to exist in true valgus, although at times in more severe cases there has appeared to be, and in one instance was, a contraction of that muscle. That the two deformities differed in their cause: the one arising from debility without any functional derangement in the muscles, or nerves supplying them; the other arising from irritation of the brain or spinal cord, thereby causing paralysis of the anterior tibial muscle, and that these causes were generally found to be the origin of these species of deformities. That the same treatment was to be adopted in both instances, but that in those cases where paralysis still existed, recourse must be had to continued mechanical support, both to sustain the arch of the foot, and also to prevent a recontraction of the muscles, but that after the ligaments had regained sufficient strength to support the weight of the body unassisted, that the patient might be allowed to wear a common boot or shoe after the active duties of the day were over, and gave you an instance of this occurring in a patient in whom the greatest laxity of ligaments and the most extensive of motion existed; yet by retaining the foot in position for twelve months, the ligaments had recovered themselves sufficiently to enable the patient to adopt the course mentioned, that of leaving off the support in the after part of the day.

We come now to consider another species of deformity or distortion of the foot (viz.) talipes calcaneus, so named from the posterior extremity of the os calcis pressing upon the ground in walking, the foot being kept in the flexed position unaccompanied with lateral distortion, or at least so slight as not to be considered as such. In talipes calcaneus, then, you have little or no malposition of the bones, the deformity being rather an extreme amount and permanent condition of one of the natural motions or positions of the foot, and this being the flexed position. In those cases I have enumerated, you have, it is true, the extreme instance of the natural position, but you have

also more or less displacement of the bones themselves, and more or less alteration of the ligaments, they being either contracted or elongated. In some cases of talipes equinus, however, you have very little displacement of the relative position of the bones, and it is a circumstance worthy of notice, that in these two deformities, the one being directly the reverse of the other, that they should correspond in this particular—viz. being each an extreme of a natural position, unaccompanied with any other derangement in the bones, &c.; the one being the greatest amount of extension of the ankle-joint, *i. e.* in its complete form; the other the greatest amount of flexion. There is, however, this important difference, viz. in talipes equinus you most frequently find paralysis co-existing and originating from various causes, both local and general. But in talipes calcaneus we have but one cause, and that one arising during uterine existence, it being a congenital deformity. It consists, then, in the more or less complete flexion of the foot, unaccompanied with paralysis or loss of power in the gastrocnemius; but the anterior tibial muscle is contracted, together with the extensor pollicis longus, the extensor communis and peroneus tertius; in fact, the whole of the muscles whose tendons pass over the anterior surface of the ankle-joint; and owing to the integrity of the functions of the gastrocnemius and the muscles situated behind the joint, you have none, or scarcely any, deviation to either side, the patient walking on the posterior extremity of the os calcis. I have never yet met with the deformity in the adult, the cases presenting themselves being in infants and young children, and it is perhaps the most rare deformity met with, at least we have hitherto found it so. You will generally be enabled to bring the foot by the hand to a right angle, and occasionally below it, but on removing the hand the contraction of the muscles immediately draws the foot up again, and maintains it so. There is no want of muscular development in infants, although this must undoubtedly occur if the deformity be allowed to continue. I imagine that cases which have not been treated in early life have been subsequently relieved to a great extent by the effects of the weight of the body in walking, pressing up the heel and keeping the foot at right angles, and the gastrocnemius retaining its functions would assist during the efforts of walking; at least, this is the only reason I can assign for not having seen this deformity in the adult. It is unquestionably the most simple distortion to treat, at least by operation, which I should always recommend you to adopt, being comparatively painless, and after the division of the tendons most easily brought into an extended position. The plan I have adopted

FIG. 1.

An illustration of talipes calcaneus, taken from the cast of a child five weeks old.

FIG. 2.

The above after five weeks of treatment, which consisted in the division of the anterior tibial and extensor proprius pollicis, extensor com-

munis is the following : to pass in a small sharp-pointed knife on the inner side of the extensor communis, beneath the tendons of that muscle, and also that of the peroneus tertius, and to divide them ; then to introduce the knife on the outside of the anterior tibial and extensor pollicis tendons (which you will find raised from the joint) ; pass it inwardly (as it regards the leg) beneath them, turn the sharp edge of the knife to the tendons, and divide them ; you will then avoid the risk of puncturing the anterior tibial artery, which, although it might be compressed easily, had better be avoided : at the end of three or four days apply a straight splint from below the knee to about the length of the foot below the extremity of the os calcis, having

munis, and peroneus tertius ; afterwards extending the feet by means of the splints mentioned.

a hole cut in it to prevent pressure on the heel, and the whole being well padded and secured throughout its full extent, above the ankle-joint, by means of strapping, first bandaging or supporting the foot by means of adhesive plaster. You then have full power to extend the foot, without fear of displacement of the splint ; by passing a strip or strips of adhesive plaster over the anterior portion of the foot and passing it round the extremity of the splint : in this way, by keeping up the extension daily, which is done with the greatest possible facility, you will in a very short time, and without much, if any pain, bring the foot to its full extended position : after you have done so, it is as well to keep it in this position for a few days,

when I would recommend you to remove the splint and allow the mother to apply the bandage over the splint night and morning, giving the child an opportunity to exercise the foot for an hour or more each time, and when the tendency to contraction is gone, leave off the splint altogether during the day, and allow the child to wear a boot well fitted, so that the support may be uniform to the foot and ankle. There is nothing more simple or more easily accomplished than the cure of this species of deformity, in the whole range of orthopædic treatment.

I have extended the foot in this way without operating, but after the removal of the splint for any length of time the contraction has returned, which I have not found to be the case after section of the tendons with ordinary care.

You will perceive that I have a great preference for tenotomy in all cases where contraction exists, whether in infants at the earliest age or late in life; and the preference arises—1st, from the facility with which it is accomplished; 2dly, because it incurs comparatively no risk, and scarcely any inconvenience; 3dly, because you at once overcome the principal resistance, and render the after-treatment painless to the patient, and comparatively easy to the attendant, independently of which, the child is not subjected to such constant confinement of the limb, which is absolutely necessary when you do not have recourse to an operation; and it must be borne in mind, that the very confinement necessary to keep up constant stretching on the contracted muscles, at the same time renders those not contracted passive, and thus no opportunity is given for development, which alone can take place by exercise; whereas, after you have overcome the resistance by means of the operation (which is shortly accomplished in infants), you can allow exercise to be taken for a certain time during the day, and this, even in infants, must have a most beneficial influence; for although the child cannot walk, yet the will is as active, and the various motions of the extremities are as numerous and frequent, or even more so, than at any period in after life. This exercise is of the greatest possible importance to the development of the infantile muscles. I operated on an infant about four months since for the deformity last mentioned; and within a month from the time of the operation the splint was omitted during the whole of the day, and the child exercised the various motions of the joint with its natural facility; and from that time to the present no trace of recontraction has shewn itself; whereas, had not the tendon been divided, the foot must have been fixed perhaps for months, and the muscles of the limb below the knee kept very nearly, if not entirely, in

a passive condition; for although the child would instinctively direct its efforts to escape from the confined position, yet the motion must of necessity be so limited, that little or no beneficial effect could be anticipated as regards muscular development.

I must now draw your attention to another species of deformity of the foot. It is a compound of talipes calcaneus and talipes valgus, and is called talipes calcaneo valgus;

FIG. 3.

An illustration of talipes calcaneo valgus, in which may be observed the absence of the projection of the os calcis, and the great increase of the longitudinal arch, with the approximation of the little toe to the outer side of the os calcis.

and although its name is derived from the above-mentioned variety, and that it is in some respects analogous to them, yet I shall endeavour to shew you that it is totally different as to its cause and in its results. By talipes calcaneo valgus, then, you will understand, 1st, a falling of the posterior extremity of the os calcis (vide fig. 3); 2dly, an eversion of the whole of the anterior portion of the foot. The posterior extremity of the os calcis being approximated to the anterior and inferior portion of the foot; the length of the foot being diminished more or less, according to the time the patient has been afflicted with the deformity, and its severity: you have, then, the longitudinal arch of the foot increased,—the ligaments on the dorsum being more or less stretched and elongated, those of the sole, and the whole of the tissues, muscular and tendinous, contracted. It is non-congenital, and owes its origin to cerebral or spinal irritation, or disease producing paralysis, either of the gastrocnemius alone, or of the entire limb; upon recovery from which the gastrocnemius will be found very generally perfectly paralysed; and if you will direct your attention to this point, you will perceive at once the mode by which this deformity is caused. The os calcis, as you are aware, has inserted on its tubercle the gastrocnemius and plantaris muscles, by which its position is maintained, and by those muscles alone. If, then, this muscle loses its power, of course the os calcis can

no longer maintain its position. It has also the strongest ligament of the sole,—the plantar fasciæ and muscles attached on its anterior inferior surface; so that these muscles and ligaments, losing the firm fulcrum upon which they act, the one contracts passively from its position; the other, by their natural healthy action, have a constant tendency to draw down the posterior extremity of the os calcis, whilst the anterior tibial, together with the common extensor and extensor pollices, having no opposing power, draw up the foot altogether, the peronei everting it; and thus the patient is thrown almost entirely on the posterior extremity of the os calcis and inner ankle, from the increased length occasioned by the constant

stretching of the internal lateral ligament; and you will find the foot, as in other instances mentioned, especially of talipes equino-valgus, only much more severe, with an extreme amount of lateral motion, and constant weakness and instability of the articulation. It is frequently combined with paralysis of the whole limb, the contracted muscles excepted, and, of course, atrophy to a greater or less extent in all instances. In some cases you will find the gastrocnemius has, to a limited extent, recovered its power of motion, and no concomitant paralysis; but this is the exception, and of very rare occurrence. I have, however, met with it in a few instances. There is also the same reduced condition of the natural tone, and

FIG. 4.

An illustration of talipes calcaneo valgus, in which the gastrocnemius had recovered itself, occurring when the patient was two and a half years old, without any previous illness. The child was put to bed in apparently perfect health, and when taken up in the morning was found to have lost the use of both lower extremities, which continued for three or four days, when the opposite extremity recovered its lost power. The leg represented in fig. 4 did not recover motion for three weeks; at the end of that time, however, the child could again walk, but with considerable lameness, which continued to the time of my seeing her, al-

FIG. 5.

though the usual means, viz. embrocations, friction, &c. had been freely used.

The tendons of the extensor communis, peroneus tertius, brevis, and longus muscles, were divided, and extension and adduction maintained by means of Scarpa's shoe for ten weeks, when the foot was restored to its natural form and position, as represented in fig. 5, and the patient could flex and extend it at will, without any lateral deviation. She wears, however, a boot, with an upright support attached, to prevent a return of the deformity, while the ligaments are gaining strength in their normal position.

liability from slight causes to wounds or chilblains, the limb being incapable of maintaining its proper temperature, even during the summer months; in fact, you have the usual concomitants of a paralytic limb. The inconvenience occasioned by it is very great, as the patient possesses scarcely so useful a limb as a wooden leg would afford, as with

the wooden one he would at least possess firmness; whilst with this deformity, unaided by artificial support, he has none whatever. The weakness and pain experienced in walking, from the relaxed condition of the ligaments in severe cases, are very great, and the lameness very considerable, as there is no available motion in the

ankle-joint. In some cases you will find the weight of the body thrown entirely on the posterior surface of the os calcis, and the front part of the foot completely off the ground, the leg presenting a straight line throughout its entire length; when, on feeling for the tendo-Achilles, you will find, as it were, a small cord, lying perfectly loose behind the ankle-joint. This, I think, can scarcely be called structural *lengthening* of the muscles, although there is a degenerated condition of the muscular fibre, which degenerated condition is consequent upon the paralysis and constant elongation of the muscle to its full natural extent. And this appears to me to be an argument against structural shortening; for the greatest amount of contraction met with does not exceed the amount of lengthening which the muscle admits of, when paralysed from disease either at the origin or in the course of the nerves supplying it. Where, then, I would ask, is the *innate* muscular action? But to return:—

In these cases, as you must have anticipated, when paralysis of the gastrocnemius is present, our treatment can be only palliative; we can remove deformity, but we cannot give power. The first thing to be done is to endeavour to extend the foot, and to force the os calcis up again into its longitudinal position, which you will accomplish by dividing the contracted muscles, and extending the foot precisely as in talipes calcaneus, keeping up, however, a greater and more permanent amount of pressure on the dorsum, with or without the pad beneath the os calcis. It will assist you if you divide also the plantar fascia, and as much of the muscles in the sole as you can easily with safety do; you will then keep up extension of the joint to enable you the more effectually to increase the distance between the os calcis and anterior extremity of the metatarsal bones, and in this way gradually raise the posterior extremity of the os calcis, which you will find is almost perpendicular. You must proceed slowly, and with care, for the same reasons I pointed out to you in a former lecture, when the deformity was connected with paralysis; and after you have restored the position of the foot, you will order a boot and iron, with a stop-joint to prevent flexion, thus always keeping the foot at a right angle, giving the patient the opportunity of extending to a greater extent in the movement occasioned by walking on uneven surfaces, or down an inclined plane, which will assist in keeping the os calcis in position.

There can be no prospect of the patient ever being able to do without the support, and you will do well to prepare him for this, by informing him that he must wear it for life, or until a remedy or cure is discovered

for paralysis which has occurred in infancy, and been of some years standing. They will, however, walk with comparative ease and comfort, and be enabled to undergo almost, if not quite as much walking exercise as persons in general, but of course with more or less lameness. In those cases where there is no paralysis, although it has generally existed, you will, with attention to the position of the foot, be enabled to perfect a cure, and in course of time the patient will be enabled to walk without any assistance, and possess as useful a limb, to all intents and purposes, as its fellow which has not suffered. You must, however, adopt here, as in other instances, the greatest care and perseverance, as the cure depends on the position of the bones and ligaments being constantly maintained during the time exercise is allowed, and until all trace and tendency for the foot to assume its malposition has ceased. I may mention to you a mode of treatment which has been adopted, and which we once tried at this Institution, viz. the removal of a portion of the tendo-Achilles, say half an inch, or an inch, placing the two remaining ends in contact, and keeping them so for a length of time. I can imagine it possible to improve a patient much in this way, provided the two ends are kept in contact, or nearly so, for a length of time; but this is very difficult to accomplish, unless you have the patient entirely under your control, which you can scarcely expect to have as an out-patient, and the object to be gained is not sufficiently important for us to keep them as in-patients during the period necessarily required, because should we succeed so far as to give a firm natural support to the os calcis by this method, we could not give power, and even then recourse must be had to artificial support, and I do not see in what way a patient would be benefitted, who, in either case, must use the same means, or nearly so, during his life. In the case I have alluded to, I removed about two-thirds of an inch of the tendon, by making an incision directly over it, and exposing the sheath, laying it open, and with a hook raising the tendon; then with a knife removing the above-mentioned portion; but he being an out-patient, was necessarily obliged to be brought to the Institution, and although every care was taken that could be, under such circumstances, yet the foot was scarcely ever found in the position in which it was placed, in consequence of the constant moving occasioned by his being brought to the charity. I do not, therefore, consider it a fair trial, but for the reasons stated it is not an operation I should recommend, as you may obtain all the ends desired or expected without it.

MEDICAL CASES.

BY SOMERVILLE SCOTT ALISON, M.D.

Physician to the Northern Dispensary.

(For the Medical Gazette.)

1. *Limosis areus. Small Stomach.*
2. *Ossification of Gall-bladder.*
3. *Hypertrophy of Heart: white liver, &c.*

JULY 4, 1844.—Ann Wells, at. three months, was at birth a fine healthy child: when a month old she lost the mother's breast, in consequence of the nipples being diseased, and was fed upon baked flour, arrow-root, milk, and the like. For a month no symptom of disease was remarked, but at the expiration of that time the child began to vomit her food occasionally, and to assume an emaciated appearance. The vomiting has continued to the present time, and the emaciation has rapidly progressed to its present frightful extent. The child is strikingly attenuated, the features are much shrunk and the muscles of the face are corded. The countenance much resembles that of a very old person; the eyes are bright, active, and imploring. The mouth gapes almost without ceasing, the face is projected forward, an imploring cry is uttered, and the eyes seem to entreat for food with the utmost urgency. The appetite of the child for food is insatiable: except when sleeping, she is either in the act of feeding, or crying and gaping for food. Only part of the food is rejected by vomiting. Much fecal matter is passed, sometimes light yellow, and sometimes green. Urine is natural in quantity. The pulse is rapid. Thorax resonant on percussion. Abdomen dull above umbilicus, resonant beneath it.

7th.—The little patient died last night. This evening examined the body. The liver was healthy, and the mesenteric glands were free of disease. The stomach was much reduced in size, two inches in length; between the longer and smaller curvature, at the cardiac extremity, it measured three-quarters of an inch; at the pyloric extremity a quarter. The coats of the stomach were considerably thickened, but in no part were undue vascularity, discolouration, or ulceration, found. The pyloric orifice was less than usual, but not more reduced than the other parts of the organ. The rugæ of the stomach

were larger than usual; they lay flat, and resembled the very fine plaiting formerly in use for the fronts of shirts: each ruga was fully half a line in breadth. The entire stomach weighed one and a half drachms. The small intestines were much contracted also. The colon was distended with flatus, and was an inch and a half in diameter. The gall-bladder was distended with green bile. The contents of the thorax were perfectly healthy.

When this patient was presented to me, I was much struck with the extreme emaciation. The child had the appearance that one would look for in a case of absolute deprivation of food. The child had been under medical treatment before, and the parents had the impression that the child laboured under mesenteric disease. I was not satisfied that mesenteric disease was present, and determined, if possible, to examine the body after death, which was obviously near at hand.

The great diminution in the size of the stomach and small intestines seems to be well worthy of being recorded. The writer has not met with any instance of so extensive a contraction of these parts. A contracted condition of the stomach is common, he believes, in cases of starvation, and also in diabetes mellitus. The urinary bladder is not unfrequently seen in a state of great contraction, and this condition the writer frequently saw to a remarkable extent in the bodies of those who died of malignant cholera during the great epidemic of 1831 and 1832, when he was clinical clerk in the Castle Hill Cholera Hospital at Edinburgh.

The diminution of size of the stomach and the small intestines in this case, is not the result of inflammation. It is not due to any morbid alteration of the mucous membrane, but is obviously referable to unwonted contraction of the muscular fibres. Undue irritability of the stomach and small intestines had resulted from the introduction of improper and irritating articles of diet, at a season when nature has prescribed the maternal milk as the only proper food.

The baked flour and arrow-root were not sufficiently irritating to induce inflammation of the mucous coat, yet they sufficed morbidly to affect the muscular fibres, and provoke them to undue contraction. The muscular fibres thus

affected by a cause in hourly operation, at length assume a permanently contracted condition, and prescribe a diminutive size to the entire organ.

The denial of the human breast to the infant was the cause of this child's illness and death. The restive stomach immediately upon its receiving food made strenuous efforts to expel it: part was rejected by vomiting, while part was hurried on through the remainder of the alimentary canal, and expelled by stool. The short sojourn of the food in the stomach was incompatible with healthy chymification, and the rapid passage of the ill-digested aliment along the small intestines was no less adverse to the elimination and the absorption of the chyle. Hence the emaciated condition of the patient, and hence the insatiable hunger. There was constant waste of the body, and only a very imperfect repair.

That the emaciation and hunger did not depend on diabetes, is sufficiently established by the urine having been only in moderate quantity, by the soft and moist condition of the skin, and by the frequent stools.

It seems to the writer probable that this condition of the stomach and small intestine may not be very rare. He is inclined to think that a similar condition, though less in amount, may exist in some infants affected with vomiting and wasting, consequent upon unnatural errors of diet. May not some children supposed to be labouring under enlargement of the mesenteric glands be similarly affected? The question is not an idle one, for the affection of the alimentary canal is curable under proper diet and management. In the body of a child five years old, who died of phthisis pulmonalis and mesenteric disease, the writer within the last few days found the colon consisting of alternate dilatations and contractions; the dilated parts or pouches contained faeces, and the contracted parts were empty, thickened, but free of ulceration.

The absence of mesenteric disease in this case, is doubtless connected with the absence of ulceration in the intestinal canal. Had ulceration or an irritable condition of the mucous membrane of the intestinal canal taken place, then it is probable that disease would have been developed in the mesentery, either by the communica-

tion of irritation along the lacteals, or by the transmission of irritating matters in their interior.

Voracity as a disease has been noticed from the earliest times. The Greeks paid much attention to it, and gave it many names. They were, however, not very successful in its treatment. Galen recommends frequent and small doses of brandy. Little is known of the condition of the stomach in these cases. Dr. Mason Good thinks the disease is usually owing to some error in the structure or position of the stomach, by which means the food passes out of this organ as soon as it is introduced into it. In a case related by Ruysch the diameter of the pylorus was considerably enlarged from relaxation. Dr. Good says that in some instances the pylorus has been changed from its natural position to a more dependent one.

Drs. Hodgkin and Carswell both allude to a diminution of the human stomach. The former writer says, the stomach is sometimes much reduced in volume, in cases in which little has entered it for a considerable length of time. He connects its occurrence for the most part, with stricture of the œsophagus, or with a state of extreme irritability of the organ itself, allowing it to receive but little, and almost invariably and immediately rejecting that.

It admits of question whether this condition of the stomach should be styled atrophy or hypertrophy. There was a diminution in the size of the organ, and doubtless the weight was below the natural standard; still the walls of the stomach were thickened, and there was the reverse condition present, to inactivity of the organ. In the meantime I would propose to denominate the stomach in the morbid condition, "the small stomach."

It may not be out of place to notice a practice which prevails to a considerable extent amongst the lower classes in London, of mothers weaning their infants at a very tender age, for the purpose of suckling other infants. The mothers propose to make a little money, and for the sake of this the health of their offspring is injured. The bargain between the nurse and the friends of the child to be suckled, generally stipulates that the nurse's child is no longer to be applied to the breast.

The writer has not unfrequently seen

with pain, the infant of the nurse pining for want of the breast, and suffering materially from irritating food, while another infant occupying its place has been flourishing upon the milky formation. This practice may to a certain extent be a necessary evil, yet there is no doubt that the practice is of far wider range than the necessity, and it would, therefore, be well becoming in every practitioner to discountenance a practice which assuredly destroys many infants in the humbler ranks of society. It would be well to point out the coming evils to the parent, who is really often more ignorant than unfeeling. There can assuredly be few christian mothers who would willingly and knowingly sacrifice the health and welfare of their offspring, and be instrumental in their death, for the sake of a little money. It is true that poverty may urge. But in this land it is, or it is said to be, a principle that no man need die of hunger. We believe this sacred law to be part of our system, though doubtless occasionally infringed. Shall it then be tolerated that the tender babe shall be driven from its mother's breast, and thus starved, or poisoned by unsuitable diet? Let us discountenance the practice, and let us stigmatise the mother as the *Δυσμενής*, *Mater suo nomine indigna*, who would knowingly destroy her infant. Such poverty as could justify the destruction of a child's health can scarcely be supposed to exist. If it ever do exist, it has urgent claims for instant relief. However, the wrong is not confined to the humbler classes the higher ranks are a material party in the mischief. It is their gold, it is their love of pleasure, which forms the root of the evil. In a word, they should beware how they corrupt these placed beneath them, and use their means to the destruction of human virtue and the perpetration of injustice to helpless babes.

The treatment of the small stomach of infants consists in restoring the breast. If this is impracticable, from the sickness or death of the mother, or from inability to procure a substitute, the infant should be fed exclusively upon an imitation of the human milk, prepared by mixing equal quantities of cow milk and tepid water, with the addition of white sugar, in the proportion of 10 parts to the 100 of milk and

water. No other food whatever should be given, even though the child be twelve months old. When the child exceeds that age, the milk may be made stronger, and some arrow-root may be added.

Under the use of this imitation of human milk the writer has of late seen several children restored to perfect health who were fast running towards the grave by the too certain paths of diarrhoea, vomiting, irritable and angry mucous membranes, and the cramming of food on the part of parents; food which, even in health, they would have some difficulty in digesting.

Ossified Gall Bladder.

Mrs. E., æt. 79, died under my care, on the 28th February, 1844, of an attack of acute bronchitis on left side. The disease lasted eight days. The patient had been singularly healthy throughout life, had never suffered any symptoms of bilious disease, and was of very temperate habits. Two days after death the body was examined. The skin was of a lemon hue; nothing beyond a sallowness of the integuments had been noticed during life. The usual morbid appearances of bronchitis were found. With the exception of the gall bladder, the contents of the pelvis and abdomen presented their natural characters. The gall bladder was white or greyish, resembling fresh putty, hard and resisting to the touch. It was distended with fluid bile: the cystic duct was obstructed with solid cholesterine. The outer coat of the gall bladder was greatly thickened, and contained much phosphate of lime. The gall bladder was very firmly attached to the liver. No signs of inflammation, either old or recent, were discovered in the bladder itself, or in the surrounding structures. This case is not without some value as forming a contribution to the morbid anatomy of the gall bladder, and proving, as it does, that extensive ossification may occur independently of inflammatory action being manifested during life.

Hypertrophy of Heart; Ascites and Atrophy of Liver.

June 26, 1844.—J. W., æt. 61, cabinet-maker, of middle stature, well formed, of dissipated habits; has drank spirits to excess; has been exposed much to cold and wet; has suffered several attacks of

acute rheumatism: three years and a half ago became affected with palpitation and other symptoms of disease of the heart. He has been steadily becoming worse, and of late the abdomen has become the seat of effusion. The patient is very ill and in great distress; is compelled to sit up in bed in order to respire with some measure of freedom: the situs of heart cannot be made out distinctly on account of the great accumulation of fluid in the abdomen; the sounds of the heart are blowing and grating; there is no fremitus; catarrh; pulse is 120, weak, and feels as if the arteries were only partially filled: head is oppressed: digestion indifferent; stomach filled with flatus; veins are somewhat distended; no hæmorrhage: previous to heart affection lost blood by piles, but not since the accession of this disease: has never had jaundice, but the eyes have a green hue; stools reported to be generally pale, sometimes dark and scanty; urine scanty, and contains a little albumen. The abdomen unusually large; fluctuates freely; the liver cannot be felt.

To take squill and blue pill at night, and a mixture composed of Spirits of Nitric Ether, Tartrate of Potash, and Infusion of Broom-tops.

29th.—The patient died last night. The body was examined this evening.

Thorax.—The lungs were freely attached to the pleura costalis by old adhesions. The heart was adherent in front to the pericardium by adhesions requiring the scalpel for their division. The heart was greatly augmented in bulk; the walls were thickened and the cavities increased in dimension; its weight was 25 ounces (16 ounces to the lb.) The aortic valves were thickened; two of them contained bony deposit along their edges; they would neither shut nor open completely. The mitral, pulmonary, and tricuspid valves, were healthy. The cavities of the heart were filled with blood.

Abdomen.—The omentum was much shrunk, and had evidently been the seat of inflammation years ago. The liver was much atrophied, and was retracted and hidden under the false ribs. It weighed two pounds nine ounces. The exterior was perfectly white, and resembled wet parchment or dressed sheep's skin. The white appearance arose from the peritoneal

covering being greatly thickened, being nearly a line in thickness: the thickened peritoneal covering was readily torn from the proper liver structure: the liver structure was rather harder than natural, and presented a little of the nutmeg character. The gentleman who conducted the dissection searched for the gall bladder, but not finding it, concluded that it was absent: there was certainly no gall bladder to be seen, but it was suggested to him to cut down across the usual site of that organ: this was done, and the gall bladder, tightly bound down by the thickened peritoneal covering, was discovered. It contained no bile. The kidneys were, with the following exception, of the natural size, consistence, and colour: the right kidney presented on its posterior aspect a tumor about the size of a pigeon's egg, containing purulent matter. The investing membrane of the spleen was greatly thickened, and appeared to have compressed the contained viscus, which was unnaturally firm. The fluid in the abdomen amounted to several gallons, and contained much albumen.

The reduced bulk of the liver forms a prominent object in this case, and contrasts well with the greatly enlarged hydatid liver, which the writer described in a late number of the LONDON MEDICAL GAZETTE. So small, and retracted under the false ribs, was the liver, that it was not immediately recognised upon opening the abdomen. The absolutely white colour of the organ formed another striking feature. The internal structure of the liver presented nothing more than signs of congestion and wasting: there were to be seen no granular deposits. The surface of liver was perfectly smooth, and in every part destitute of any approach to the rough and tuberculated condition found in cirrhosis. The morbid condition of the biliary organ depended entirely upon thickening and contraction of the investing membrane, consequent upon antecedent inflammation, probably of a subacute character. This view of the case is supported by the atrophied or shrunk condition of the omentum and other parts of the peritoneal membrane.

Thickening of the serous membranes has been pointed out by several morbid anatomists. Craigie regards this as a result of inflammation, but Liennec

denies its existence. The liver has not unfrequently been found to be invested by a thick membrane, but while it appears that some have regarded this as the thickened peritoneal covering, others amongst whom are Carswell, have regarded it as an adventitious false membrane. The investing membrane in the above case was certainly the peritoneal covering in a state of thickening. Dr. Roots has in the sixth volume of Guy's Hospital Reports, related a case in which the peritoneal covering of the liver was in a state of thickening.

The apparent absence of the gall bladder is worthy of notice. The peritoneal covering of that receptacle, like that of the liver itself, having been the seat of inflammatory action, probably of a subacute character and of long duration, underwent a process of thickening and of subsequent contraction, and effectually bound down the invested bladder so as to efface all appearance of it. Had not the transverse incision been made, the cyst would not have been found, and it would have been concluded that no gall bladder was present. Perhaps the gall bladder existed in a similar condition in some of the recorded cases of alleged absence of this appendage of the liver.

Dr. Carswell says, that in cases of false membrane in the abdomen, the gall-bladder is contracted and nearly empty. In Dr. Roots' case, above alluded to, the gall-bladder was reduced in size, and contained bile. But none of the writers above referred to mention the gall-bladder as ever so completely bound down by false membrane or by the thickened peritoneal covering, as it was in the present case.

48, Gower Street, Oct. 18, 1844.

POINTS OF PRACTICE.

To the Editor of the Medical Gazette.

SIR,

THE signal profusion of modern medical literature makes the courage to be ignorant of a great deal absolutely necessary if we would know any thing thoroughly. Many active and zealous practitioners abandon in despair all hope of keeping pace with the press, and, annoyed at the general disposition to take nothing for granted, confine themselves to the quantum of science with which they

began their professional career, and are only anxious to accumulate "bits of practice." They are probably in the right. When a man is once well employed as a general practitioner, he has neither leisure nor inclination to investigate first principles. He must *act*; and the communication of a new and efficient mode of treating a common and well known disease is of vastly more importance to him than the most learned and philosophical treatise on the functions of nerves or the composition of the blood. "Give me a good bit of practice, and I will thank you for it, but I have no time for scientific researches," has been often said to me by a country practitioner who, by dint of close observation and natural sagacity, has made himself a very valuable instrument of good to his fellow creatures. He can cure disease, though he cannot talk about it.

Bearing this in mind, I propose, with your permission, to communicate, from time to time, some of the results of forty years' close observation of disease in several countries of Europe. I will confine myself solely to subjects that I have thoroughly ascertained, and leave all speculations to the young. They are useful as exercises of the mental powers even when they lead to no result; but a man may be very right in his practice without being able to give reasons for it. I will call my contributions POINTS OF PRACTICE; and the first shall be on a not uncommon, but a very embarrassing form of dyspepsia, of which I can find no mention by any writer. The cure is easy, or I should not think a notice of the malady worth communicating.

1. A Form of Dyspepsia.

It begins with the usual symptoms of flatulence and sense of oppression after eating — *almost immediately* after a full meal, by which it is to be distinguished from defective digestion in the duodenum. There is no headache.

It affects almost exclusively those who neglect proper exercise, and indulge in pastry and dishes that are fried. As it advances, the distress produced is excessive; there is a sense of constriction at the pit of the stomach and at the sides of the neck; and if the patient move soon after a meal, he readily regurgitates the food he has eaten — not with a sensation of sickness,

but in the mode we see in ruminating animals. Any attempt to prevent this gives pain; but if he walk briskly up hill, or up stairs, for ten minutes or a quarter of an hour, he gradually rejects two-thirds of his dinner, and is then perfectly well.

When he allows the food to remain, there comes on, in the further progress of the case, symptoms exceedingly like angina pectoris. There is an intermitting pulse; pain in the sternum, which becomes exceedingly tender to the touch, and a general feeling of lassitude; with an aching of the arms similar to that which arises after taking opium. Eructations are frequent and excessive, after each of which the pulse immediately becomes regular, and there is an universal sensation of uneasiness which it is impossible to describe. There is also a feeling in the throat like the globus hystericus.

An immense variety of symptoms will immediately suggest themselves when the cause of this annoying malady is stated. It is the accumulation of food in the œsophagus, which will sometimes take place to an enormous extent. It arises from defective power in the œsophageal plexus of nerves, and also from a constriction of the orifice in the diaphragm, or from a combination of both. It would make too long a communication to detail the mode in which I ascertained this; but of the fact I am certain. Each mouthful of food is mechanically driven down by that which follows it. At the beginning some goes into the stomach; but the power of deglutition seems to last only a certain number of minutes, and to be exhausted long before the appetite is satisfied. The food which remains in the œsophagus, not being subjected to the vital action of digestion, takes on the chemical action of fermentation; and we may easily conceive the effect of a large foreign substance, and the gases thus generated, occupying the space which should be devoted to the lungs and heart. That portion of the œsophagus which is under the influence of volition performs its proper functions; but the involuntary portion seems to remain a mere flaccid tube, incapable of taking up its duties. Many hours will elapse in this distressing state; and the food, when rejected, is perfectly unchanged.

The remedy is obvious. Eat fre-

quently, and in very small quantities at a time; use very active exercise; and undergo an occasional fast of twelve or fifteen hours. Wait some hours after rising before the breakfast is eaten; and in very aggravated cases let the food be a kind of rich panada, made of a very strong decoction of lean meat and crust of bread. Avoid all fried things; take weak cold spirit and water rather than beer or wine; use cayenne pepper freely; keep the bowels open by warm laxatives, as the *beanne de vie*; and, above all, give way always to the desire of regurgitation; promote it by violent exercise, and never let the œsophagus be distended if it can possibly be avoided. When the sense of oppression is entirely gone, a basin of warm tea (not weak) will be of great service; and if, in spite of advice, the patient will occasionally indulge in a hearty meal, let him bear in mind that he must begin again *de novo*. The dilatation of the tube can only be overcome by a steady perseverance in the plan, and one excess puts him back to the point he started from.

It does not appear that the stomach often partakes of the disturbance: digestion is perfect, and there is every appearance in the evacuations that all the other functions of the body are in order.

The danger is, that when seen for the first time it should be considered as disease of the heart,—ossification, or angina pectoris. The practitioner may easily commit himself by a premature opinion.

There is no kind of exercise so well adapted to the disorder as the game of tennis; but this is accessible to few. Fives or racket would be a good substitute.

A. L. WIGAN, M.D.

CONTRIBUTIONS TO HYGIENE, WITH PARTICULAR REFERENCE TO THE SOLDIER.

[Continued from p. 113.]

MILITARY HYGIENE.

Punishments; their Moral and Physical Effects.

IN practice, the principal duty of a medical officer upon a punishment parade, is to prevent the delinquent from successfully feigning a disability, for

the purpose of escaping corporal infliction.

Flogging is, by a small minority of officers, believed to be neither beneficial in reforming delinquents, nor in effectually warning others from committing breaches of discipline; indeed, in their opinion, excess of punishment seems to promote the commission of offences. Mr. Harriott, who was for some time Judge Advocate in the Madras Presidency, relates a case where punishment was obviously injurious. "Private King," says our author, "who was a good clerk, and a clean smart soldier, had been repeatedly promoted, and as often reduced in consequence of intemperate habits. When sober, he was a pattern to the regiment for excellent behaviour and exemplary conduct. Repeated punishment rendered him insensible to shame, and hardened his disposition against reformation. On one occasion he received 150 lashes; and to prove his hardihood, he held the halberds without being tied up, and received the punishment without flinching. The commanding officer, who had only recently joined the regiment, addressed the men, in a pathetic soldier-like manner, on the subject of crimes and punishments; by which the whole parade became deeply affected. King, whose back was streaming with blood, folded his arms across his breast, and listening, apparently with ease and composure, until the address was finished, coolly asked the commanding officer how many lashes he thought he (King) might have received since he had the honour of serving the Company? 'Too many,' replied the Major, 'I fear, to have done you any good.' Continuing in the same position, King replied, 'I have had the honour to receive just 950; and if you please, Major, I will take another 50 now, just to make the score even, and let it stand to the next account.'

"Both officers and men stood aghast at this breach of military decorum. He was forthwith ordered to the hospital, with an assurance, that should he again subject himself to the sentence of a court martial, means would be taken to punish him more effectually. King's subsequent fate deserves to be mentioned. In a short time he was brought to trial for drunkenness, disobedience, and striking an officer. He was found guilty; and it was generally expected

that his punishment would be extremely severe. The sentence, however, was to receive 50 lashes only, but on his breech like a boy. King was so affected at the thought of being thus disgraced, that he was taken ill, and sent to hospital, where he remained several months. It was indeed, the general opinion, that he would have continued there until he died; but it so happened, that a man was sentenced to be shot, and on these occasions it was usual to make a request through the medium of the Judge Advocate, for the pardon of prisoners confined or sentenced for minor offences. By this means King was pardoned. He left the hospital in a day or two, and subsequently behaved so well, that in a few months he was promoted to a halberd, and had long the credit of being one of the best serjeants in the army."

It is contended by a majority of military officers, that the severity which characterises our military enactments and usages is essential to that degree of subordination which should prevail in the British army, while not a few entertain a contrary opinion. The arbitrary powers placed in the hands of officers are, it must be admitted, often greatly abused; and to those who look beneath the surface of things, it will be obvious that the stern and rigorous rules of military discipline are frequently partial in their operation. There is a large amount of silent but undeserved suffering in an army, the individuals of which may neither have the right to complain of, nor the power to resist, the harsh treatment to which they are subjected. An example illustrative of the truth of this observation may be given.

It is customary in the army to perform the barrack-room fatigue duty in rotation; and it is part of that duty to carry the messes from the cooking-house to the rooms; for this purpose, the orderlies, as they are called, fall in, and are marched, under the command of a non-commissioned officer, to the cooking-house, a few minutes before the bugle sounds for dinner. It happened in the — regiment of Dragoons, while serving in India, that on the orderly men falling in one day, previous to marching off for fatigue duty, a private dragoon, named Kennedy, was reported absent; a moment after, he made his

appearance, and stated he was going to wash his hands at the pump at the rear of the barracks,—not more than a few yards distant,—when he would return and join the party. “Fall in immediately, sir!” shouted the corporal, a tyrant in his petty way. “When I have washed my hands,” replied Kennedy, as he ran to perform his ablution. This was all that passed on the occasion. The vindictive corporal immediately placed him under arrest, and a court martial having been called next day, to investigate the charge, Kennedy was found guilty of a breach of discipline, and sentenced to receive 300 lashes, which were duly administered in the riding-school, in the presence of the assembled regiment. The commanding officer of the corps concluded a long address to the men, with the following remarkable observations:—“And now, sir, I have long waited for this opportunity of teaching you better manners, and a proper respect for military authority. You are well known as an old, and I fear incorrigible offender, and are sufficient to spoil the younger soldiers in the regiment, by your example. I will teach you, and all who hear me, that fatigue is a duty, and a very important one too. I trust this will be a warning that you will recollect to the last hour of your existence. Take him down.”—(*Life in the Ranks*, p. 188. London, 1843.)

How far such a punishment was required, or calculated to prevent military delinquencies, I leave my readers to judge. “Respect for authority can only be ensured by convincing those in subordinate situations that it is exercised with impartiality and discretion.”

The manner or conduct of some commanding officers, on a punishment parade, differs materially from that of others; and the same may be said of delinquents. Colonel —, where he commanded the — regiment in the West Indies, used to occupy a chair in the middle of the square, when he superintended the infliction of the cat. He had, it must be admitted, some apology for adopting so unmilitary an expedient; for, while he commanded, there were frequently from ten to fourteen men punished at one parade. The magistrates in Holland superintend, I believe, all punishments, sitting in solemn pomp close to the place where

the delinquent is undergoing the infliction to which he has been sentenced. This used, I know, to be the practice at the Cape of Good Hope. Some men do not complain while they are undergoing punishment; others complain much, and beg to be “taken down,” from the time they receive the first lash.

There are some who convert the infliction into a source of amusement, by the discordancy of their remarks with the pain they are obviously enduring. “An Irish dragoon who was brought to the triangles, not only bore the lash without wincing, but between each round administered by successive operators, was ready with some absurd remark, which converted the whole scene into a farce rather than example, neither officers nor men being able to preserve their gravity. Amongst other things he had the assurance to tell his commanding officer, ‘that he might release him, as he had now been thrashed to his satisfaction.’ He, however, reserved his best stroke for the last; for as they were casting him off from the triangles, he turned round, and with a countenance in which fun and suffering were ludicrously blended, exclaimed, ‘Ah, you may talk of tobacco, but this is the real twist.’”—(*Life in the Ranks*.)

An example of another kind may be stated. A Captain T—, of — regiment, had a *chère amie* in his barrack-room, and one evening, while he was at mess, the sentry on the officer’s quarters, seeing no immediate probability of his attention being occupied in the way of duty, pulled off his boots, and leaving them with his musket in the sentry-box, proceeded softly to visit the said *chère amie*; but, unfortunately for him, Captain T. left the mess at an unusually early hour that evening, and found the sentry in his room. The sentry was tried by a court martial for leaving his post, and sentenced to be flogged. When he had received about one-half of his sentence, he called out most lustily, “O take me down, colonel, take me down, and give the rest of the lashes to Captain T.; he is as much to blame as I am; for if he had not kept that woman in his room, I would never have left my post.”

Medical officers should be particularly cautious in regard to persons suspected of fraudulently feigning disabilities. By

the articles of war, "any soldier who shall be convicted of malingering, feigning, or producing disease or infirmity," shall "be liable, in addition to corporal punishment," to any other punishment which the court may be competent to award. Medical officers are doubly responsible in cases of suspected malingering: in the first place, because it is usually upon their evidence that a soldier is convicted; and secondly, inasmuch as they are required to certify that he is fit to undergo punishment. Medical evidence, in regard to malingering, has seldom any better foundation than inference or presumption; and however improbable the allegations of a man may appear, some doubt will generally enter into the mind of a medical officer in regard to the existence, in a greater or less degree, of the alleged disability, of which doubt the accused should have the benefit. A medical officer may certify that a soldier is, in his opinion, fit for duty, although it is believed he will rarely consider himself warranted to swear that a man is not suffering more or less under physical or mental disease,—real or imaginary. Colonel Campbell, in his "*Excursions, &c.*" gives the following account of the flogging of a suspected malingerer on board a transport, which will shew how the articles of war and the usages of the army were administered.

"Darby Star, a clean, regular, good-looking soldier, was suspected of being rather *shy*, and tried by a court martial for feigning disease. It appears that the principal witnesses for the prosecution were the surgeon and his hospital sergeant. Darby was sentenced to receive 500 lashes, and tied up to the grating at the gangway of the ship, and had 50 lashes inflicted upon him in an amazing short space of time. 'Stop,' said his stern commander; 'will you, Darby Star, confess that you are a malingerer?' Darby was speechless. 'Go on;' and the drum-major was told to see that the drummers did their duty. He received 25 lashes more. 'Stop, will you now confess?' In a very weak voice Darby protested that he was as innocent as the child unborn. 'Take him down.' But all present were told to mark their commanding officer's words; and they well knew his word was never broken. 'You, master Darby Star, shall every Monday morning receive 50 of the 500 lashes to

which you are sentenced, until you acknowledge you are a malingerer.'"

[This address resembles in some respects the spirit of a torture warrant of the sixteenth century, of which the following are two specimens. Shortly after the accession of Queen Elizabeth, the privy council directed two prisoners to be examined; and if the men should persist in denying the fact, they were "to be brought to the rack and to feel the smart thereof, as the examiners, by their discretions, shall think good for the better *haulting* out of the truth of the matter." In 1565 a letter was addressed by the council "to Lord Scrope, directing him to deal *somewhat sharply* with Nicholas Heath, to the end that he should declare why he wandereth abroad, and if he will not be plain, to use some kind of torture toward him, so it be without any great bodily hurt.]"

"Next Monday came: Darby was almost carried up from below, with scarcely an appearance of life in him, his back by no means healed, from the effects of the punishment he had received. Without further ceremony, he was again fastened to the grating. 'Drummers, do your duty,' sounded in Darby's terrified ears. I confess I really pitied him; his appearance deceived me; and I knew not what to think. Colonel D——, however, stood determined to go through what he had begun. During the infliction of 25 more of the lashes, which I noted with an unsteady hand, (Colonel Campbell, the narrator, being the adjutant of the corps,) Darby called out, in an astonishingly loud voice for so sickly-looking a wretch, that he would confess anything in the wide world if he would only be forgiven. 'Stop! you confess yourself, then, to have been all along a malingerer?' 'O yes!' groaned Darby. 'Speak out, sir, so that all on board may hear you distinctly.' 'O yes, yes,' roared Darby. 'Take him down. Now, sir, you must convince every one present that you are quite recovered; and to shew that you really are so, you must, as an old dancing-master, instantly give us a jig.' A drummer and fifer were ordered to be in readiness to play a tune; and as soon as he was dressed, Darby got on with his jig in first-rate style."

The proof of imposture in this case depends on the same fallacy which attends any confession that may be

extorted by the rack. Evidence thus obtained is a deceitful and dangerous instrument; for many persons will tell any kind of falsehood rather than undergo the torture. Besides, it should be recollected, that every healthy man who alleges that he is sick, is not an impostor; he may with all honesty believe that he is suffering under disease, and unable for duty. Shortly before the revolution of 1793, the parliament of Paris suspended two judges from their office, who had ordered the execution of a man for the alleged murder of a woman, proved only by his own confession under torture,—the woman being discovered alive within two years after the execution of the supposed murderer.

Instead of bringing an alleged malingerer at once before a court-martial, I think, with Dr. Cheyne, that a medical board, consisting of at least three medical officers of mature experience, would be found the better tribunal in the first instance, and upon their decision the ultimate measures should be grounded. It is easy to infer and to allege, that a soldier is fraudulently feigning a disability; but it is frequently very difficult to prove satisfactorily that he is not more or less affected with disease or disability. No person should be convicted of the crime of malingering unless it be very satisfactorily established by skilful and impartial testimony. A medical officer who has had the care of an alleged malingerer, and who has reported him to his commanding officer, may have so far identified himself with the accusation, as to be somewhat biassed in his opinion of the case; and consequently a court-martial will be required to estimate the weight of his testimony, according to what they may deem its real value. I repeat my opinion, that no man should be punished for a delinquency so difficult to appreciate as feigning a disability, but upon the testimony of two competent and impartial witnesses.

Numerous examples might be adduced to shew the caution which should be observed before a medical officer certifies that a man is in sound health, and fit to receive corporal punishment. In a regiment of native infantry (India) a tent-pitcher was the bearer of a note from the adjutant to the medical officer, a young man, stating that he wrote at

the request of the commanding officer, who, as well as himself, was convinced that the man was feigning disability in order to evade duty; that they sent the man to be examined, and if he (the medical officer) should be of the same opinion, the tent-pitcher was to be forthwith flogged. The man was a strong, hale, stout-looking fellow, but with a somewhat heavy expression of countenance. He complained merely of headache, and feeling languid,—and looked the picture of health; his tongue was clean, his skin was cool, but his pulse was a little lower than the average. The medical officer wisely decided that further inquiry was necessary, and the adjutant was informed that the man was not well. He died during the night, probably from apoplexy. Medical officers are well aware that serious disease may be impending, without being indicated by any external character which they are able to recognize and appreciate; and men who appear stout and well may be very ill, although they cannot state their cases clearly.—(*Medico-Chirurgical Review*, No. 79, p. 75.)

Ignominious punishments were formerly much employed, both in civil life and in the army; and among this class of punishments, the wooden horse was chiefly used in punishing soldiers. According to Grose, the wooden horse was formed of planks eight or nine feet long, laid together so as to form a sharp ride or angle. When soldiers were sentenced to ride the wooden horse, they were placed on the back with their hands tied behind them; and to increase the punishment, muskets were tied to their legs. There appears, however, to have been some variety in the mode of infliction, as may be seen by the following extract from Knox's *Historical Journal of the Campaigns in North America in the years 1757—1760*. "Yesterday a court-martial sat on a grenadier, for absenting his command when attacked by the enemy: he was found guilty of cowardice, and I think," says our author, "the particular punishment ordered for him evinces great discernment in the members of the court. Their sentence ran thus. It is the opinion of this court, that the prisoner is a notorious coward, and they sentence him to ride the wooden horse half an hour every day for six days, with a petticoat on him, a broom in his hand,

and a paper pinned on his back, bearing this inscription, 'Such is the reward of my merit;' which sentence was duly executed." (Vol. i. p. 96.)

This man conducted himself, on many subsequent conflicts with the enemy, in a manner equal in courage to the bravest of the army. Few persons are, I believe, at all times equally disposed either to attack or resist an enemy; and it may be doubted whether a coward was ever made a brave man by disgracing him. Perhaps, however, alleged cowards are punished as an example, for the purpose of rendering men more afraid of the triangles than of the enemy, and hence an attempt is made to excite courage by the passion of fear.

The Chinese adopt this plan to prevent cowardice. Among many other duties of a Chinese soldier in warfare, it is ordered that "he who wears the drum and does not advance, or who hears the gong and does not retire, shall suffer the same punishment. Strict adherence to the severities of martial law is the only way to make brave men of cowards."

Sound policy, honesty, and humanity, will it is hoped eventually lead to an alleviation of the punishments in the army. The severe punishments and harsh usages of soldiers are the results of old causes; and our generation has the honour of contributing to their improvement, while the disgrace of their existence belongs to a former state of society. We see the progress of melioration silent but sure in the army; by which means more beneficial effects will be produced than are generally anticipated*. Attention to cleanliness,

* Several examples might be stated of the abolition of severe and impolitic laws and usages in the army, owing, probably, to the meliorating influence of civilization and social improvement. For the alleged purpose of repressing immorality it was at one time a rule in the army to fine every soldier who had the misfortune to be affected with the venereal disease. A man who was infected with one grade of the disease was obliged to pay half a guinea, and for another grade he paid five shillings. The surgeon of the regiment was the informer, the judge, and the receiver-general. By the civil laws of the country, an informer, I believe, never receives above one half of a fine which is levied in consequence of his information; but in this example of military law, the surgeon pocketed the whole, and from his judgment there was no appeal. It is obvious that by this impolitic law a surgeon would be frequently led into temptation, his interest and the principles of humanity and common sense being often at great variance. Soldiers, as might be expected, did every thing in their power to evade the summary jurisdiction of the surgeon,

and an ample supply of nutritious food, will contribute greatly to preserve the health of soldiers; but humane treatment is of immense importance in preventing disease in an army; so much so, that the saying is not far from truth, that a kind captain has generally a healthy company.

As a proof of the beneficial influence of civilization, I may state, that on the 1st of May 1844, the Emperor of Russia "issued an ukase, in which (as already in the Imperial Guards), the bastinado is prohibited in the whole army, except in cases of extraordinary criminality, and that in such cases the punishment is not, as was formerly the common practice, to be inflicted at the direction of the colonel of the regiment, but by virtue of a sentence pronounced by a court-martial. Those persons who act against these orders are to be severely punished."

It is also alleged, that the King of Prussia has wisely and mercifully determined on the abolition of flogging in his dominions; and there can be no doubt, that in proportion to the justice and respect with which he treats his soldiers, they will become attached to his service, and worthy of serving him, for he will govern men, and not slaves; he will himself, by this act, reap honour not only for a deed of justice and humanity, but for the elevation of the character and morals both of men and officers.

In 1832, an excellent project for a new criminal law was published in Sweden. The enlightened authors of this proposal observe: "The experience of all periods and of all countries shews, that extremely severe punishments harden instead of deterring." In accordance with a humane view of the object and nature of punishment, the committee have abolished flogging, which, "as being of short

whose fine or punishment was a much dreaded penalty. Half a guinea, or even five shillings, was a great sum to a man whose income varied from three to four shillings a week. Many army surgeons recovered this odious assessment with much pain. The experience of many years demonstrated that the remedy was not calculated to check the immorality it was intended to prevent; indeed, in many instances the fine was found to be productive of much individual distress, and an aggravation of the disabilities of soldiers. This regulation was in full operation as late as 1795, but at what period it was abolished I do not exactly know. A similar rule obtained in the Navy, but it had been abolished before that date.

duration, is, for the individual already morally corrupted, less deterring than other kinds of punishment. In him, on the other hand, whose feeling of human dignity is not already smothered, this debasing punishment crushes those dispositions for improvement which are founded in human nature, and brings him to despair." All other degrading punishments—as penance, pillory, and stocks, are also excluded from the project, “as not conducive to the improvement of the criminal, and likewise failing to awaken in others a warning and an aversion for crime.” Frequent and severe punishments have a decidedly bad effect, in some instances by lacerating the feelings, and in others by hardening the minds of spectators.

RECORD OF CASES.

By THOMAS MAYO, M.D. F.R.S.

Physician to the Infirmary of St. Marylebone.

[Continued from p. 18.]

(For the Medical Gazette.)

On Bleeding in Cases of Congestion.

No one of our remedies is at once so uncertain, and at the same time so important in its effects, as, in a certain class of cases, the removal of blood.

The class of cases, to which I here allude, are such as it is usual to refer to what is called congestion. To systematise the groups of symptoms by which these cases are characterised, in reference to treatment, would be premature. They occur in very different illnesses, and start up occasionally under circumstances to which no nosological place has been assigned. It has, indeed, appeared to me, that the most effectual way of rendering them instructive in respect to therapeutics, would be to collect and enumerate them. This operation must precede any attempt at more philosophical views.

I shall here adduce three cases of successful depletion, where the congestion had been cerebral; and although at present I have to do with nothing except facts, I cannot neglect the opportunity here offered, of expressing my thankfulness to Dr. George Burrows, as having removed the theoretical difficulties opposed to the reception of such facts by the supposed views of

Dr. Kellie, and their real acceptance by Dr. Abercrombie and others. We are indebted to Dr. Burrows for informing us, that in the presumed absence of atmospheric pressure on the contents of the cranium, it is not a plenum in respect to its contained blood; and that we need not, in our speculations, limit the effects of depletion to the altering the *relative* quantities of arterial and venous blood therein contained.

In June, 1828, I was sent for early in the morning to the Hon. Mrs. P., a lady aged 50, apparently of a nervous temperament, and of a habit neither full nor spare. She was described as subject to head attacks, which were sometimes relieved by stimulants, but in their severer forms requiring depletion. She had the preceding night been much frightened by the sudden death of a servant. Severe pain about the vertex came on, and gradually increased in the course of the night to a very excruciating degree, accompanied by a sense of weight and by sickness. When I saw her she complained of these sensations, and of extreme coldness, which appeared to be creeping and increasing on her. The pulse was small, the visage contracted; the legs and thighs moved spasmodically.

I first relieved her, and somewhat lessened the coldness, by a little brandy and water. Then, as the other symptoms were rather increasing than diminishing, I directed that fourteen ounces of blood should be taken. The blood at first flowed unwillingly, afterwards more freely; and when this began she expressed a sense of diminished pain and returning warmth. Soon afterwards, the spasms and pain somewhat returning, I allowed about eight ounces more to flow. All the symptoms were from this moment relieved. In the course of the afternoon the action of an aperient, which I had given, occasioned syncope, and was followed by severe hysterical symptoms. In about thirty-six hours from the time at which I first saw her, she was perfectly well.

The following case I give in the words of the assistant resident practitioner at the Marylebone Infirmary:—“I was sent for on the night of the 11th of November, to Joseph Taylor, in the workhouse. I found him quite insensible; pupils much contracted;

pulse about 60, and very low; the extremities cold. The right side of the body was affected by convulsive movements, which occurred at intervals of three or four minutes, and lasted the same length of time; the left side was unaffected. I could not easily ascertain how long he had been in that state. For the last two or three days he had been complaining to those around him of a pain in the head. I gave directions for his removal to the infirmary. When he arrived there he was in a state of partial collapse; the face and extremities of a pallid blue colour; the pupils still contracted, and insensible to light; the contractions of the limbs were recurring with much force. As he appeared a strong muscular man, a vein was opened. The pulse, which I have described as low and feeble, improving under this measure, the bleeding was continued, until he had lost about fifty ounces, a considerable quantity being also spilt on the floor in consequence of the spasms, on which this loss of blood seemed to take no effect. As soon as the pulse began to give way the vein was closed. The symptoms continued, however, in every respect the same, except that the natural heat of the body had been in some degree restored. Recourse was then had to cupping on the temples. When he had lost about six ounces (*when the brain was depleted*), the convulsions suddenly ceased, and the pupils began to dilate and contract irregularly. In a short time he started up in bed, endeavoured to mutter something, and looked about him in a bewildered way. The cupping was continued until he had lost twenty ounces; he was then sensible, but could not give a collected answer."

These symptoms did not recur. The patient was brought under the influence of mercury by one of my colleagues, whose patient he was, and in the space of a month had entirely recovered.

This man, I ought to observe, had recently lived well, and drunk rather freely.

Thomas Jenkins was admitted during my week into the Marylebone Infirmary, as a fever case, of which his appearance gave every warrant. His visage was contracted; prostration considerable; tongue coated, brown, and dry. The breathing slightly accel-

erated, with some ronehus on both sides; but there was little heat of skin, and the pulse was oppressed, and did not exceed sixty. The bowels were soft and pliant, and described as open; the urine plentiful, but scalding. He also complained of heaviness and pulsation at the occiput, and the right hypochondriac region was tender on pressure. He wandered slightly in talk. As far as I could learn, he had been ill about forty-eight hours. I was induced mainly by the state of his pulse, as being inconsistent with simple fever, to direct the removal of eight ounces of blood from the nucha by cupping.

Sumat Hydrarg. Chlorid. gr. ij.; Opii, gr. 4, 6tis.

5th.—He had slept well, and was less delirious, being much relieved by the cupping. I now learn from him, that he fell down in the street insensible yesterday, but promptly came to himself. Occiput still very hot; pulse 48. The bowels have not acted.

Sumat Pulv. Hyd. Chlorid. c. Jalap. gr. xv. statim.

6th.—Much better; bowels have acted freely; pulse 54.

Perstet in usu Pil. Hyd. Chlorid. c. Opii.

7th.—Mouth affected. Some heaviness of occiput was now again complained of; but his tongue was moist and cleaner, his bowels open, and his general appearance much improved. I ordered him a more generous diet, namely, daily meat, he having had only beef-tea before. This change agreed, and the heaviness of head subsided. By the 14th of May he was well. His pulse had become 70.

In the above three cases blood was successfully removed, on a hypothesis of cerebral congestion. In the following case it was *unsuccessfully* removed, on a similar hypothesis, which turned out on subsequent inquiries to have been delusive.

Frances Page, a well-grown and healthily constituted infant, was brought into the infirmary September 27, 1844. She had passed out of an attack of measles three weeks before, and had since laboured under cough. The breathing, though not distressed, is uniformly short and quick; the aspect dull; the eye glassy; there is no evidence of pain or fever. In this state of symptoms she remained to the

6th of October. In the course of this time three leeches were once applied to the sternum: they bled freely, and relieved a slight increase of hurried respiration, which had occurred; also one Emplast. Lyttæ. In the greater part of the time Pulv. Hyd. Chlorid. c. Antim. Pulv. Conii C. aa. gr. ij. were given 8vis.

My object was to produce resolution of a state of hepatised lung, which had probably supervened, though I failed to authenticate this by auscultation or percussion, from unwillingness to expose the infant. The fact itself was, however, of the most common occurrence in those infants in the infirmary, in whom catarrh had succeeded measles, unless instantly removed.

On the 8th some pyrexia was observed, and about that time she was first heard to hoop by the nurse. The breathing was not altered; she was constantly sleeping, or irritable during her short intervals of waking.

Hirudines ij. sterno. Pt. in usu pulv. supra præscript. 4tis horis.
10th.—Emp. Lyttæ nuchæ. Pulv. 8vis.

11th.—Thoracic symptoms much the same; abdomen distended; restlessness.

Misturæ Assafoetida, ʒiv. pro enemate.
Pt. in pulv. bis quotidie.

14th.—A second enema thrown up yesterday; on each occasion restlessness quieted. The hooping is now frequent.

15th.—The fixed pupils and comatose aspect of countenance, induced me to apply a single leech to the temple. From this very free bleeding took place, with immediate convulsions and additional coma, continuing till death, which occurred at noon of the 16th.

Post-mortem.—Brain large and firm; convulsions unusually deep; no effusion in ventricles, general character rather exsanguine, but not abnormal in any other point.

Greater part of both lungs non-crepitant, of a nutmeg colour, generally softer than the usual character of hepatization; but detached lobules sinking in water. Pleura opaque, and with a remarkably soapy feel on being handled; no fluid or coagulable lymph in either cavity.

A large white polypus in the left ventricle of the heart, which was other-

wise normal; as were all the viscera of the abdomen.

In this case it may be conjectured, that the cerebral phenomena observed by me during life resulted from an imperfect supply of blood, itself in an imperfect state; and that the abstraction of a part of this supply occasioned the fatal train of cerebral symptoms which then set in.

I shall take leave for the present of this interesting subject with the following extract from the posthumous writings of Dr. Parry, of Bath, with which my own experience coincides, in its yet more extended application to bleeding in cerebral congestion.

"Difference of effect between small and large bleedings in hemiplegia.—When Dr. H., who was above 70 years of age, was seized with hemiplegia, in which he totally lost the voluntary power of his arm and leg, I ordered him to be cupped. This was done only a few hours after the seizure. While the operation was performing, when only four ounces of blood had flowed, the power of voluntary motion in his limbs returned; but again vanished by the time ten ounces had been taken away*."

The lesson, however, here conveyed must be read with caution, in regard to the inference which it may appear to warrant.

[To be continued.]

CASE OF PECTORAL DISEASE.

To the Editor of the Medical Gazette.

SIR,

I SEND the following case, imperfect as it is, because it presents some points of interest connected with the diagnosis of pectoral disease, which I think may render it worthy a place in your pages.

I am, sir,

Your obedient servant,

T. OGIER WARD, M.D. Oxon.

21, Lower Phillimore Place, Kensington,
Oct. 15, 1844.

J. N., æt. 59, postman: has drunk freely, chiefly of ale, when a young man, though latterly he has been abstemious. For many years he has had palpitations, with cough, dyspnœa, and inability to lie on the left side from

* Medical Writings of the late C. H. Parry. Vol. i. page 474.

pain in the region of the heart, unless his fist was doubled under him at that part. About four years ago, he was first laid up, and since that time his attacks have increased in frequency, severity, and duration, till the last, which proved fatal in thirteen weeks. He came under my care a year and a half ago, when he complained of cough with white viscid and frothy expectoration, dyspnœa, aggravated by going up hill, and being out in cold and foggy weather; pain under lower ribs of left side, increased by a full inspiration; part tender to pressure; violent palpitation of heart, consisting of tumultuous repetitions of the first sound, with pretty strong impulse and bellows murmur to left of sternum, but this was not always audible; extensive dullness over præcordial space; and the action of the heart visible in epigastrium and left hypochondrium; dullness, but not great, over painful portion of left side, with moist crepitation in the same part, and mucous rattle for a small space above; respiratory murmur clear in front and over right side of chest, except during some violent attacks, when there were mucous rattles at back and lower part of right lung. The moist crepitation was permanent on the left side, even where there was no morbid pulmonary affection. Pulse very weak and irregular, not so frequent as the impulse and ventricular sounds, and the weakness of the pulse always increased with the urgency of the dyspnœa and other symptoms. No regurgitation along jugular veins. Considerable fulness of epigastrium and right hypochondrium from enlarged liver. Tongue usually pretty clean, but during attacks coated over with a thick pellicle, peeling off in patches as the attack subsided; appetite bad, with thirst and some fever; œdema of the ankles; urine variable in colour and quantity during attacks, but latterly containing some albumen.

The treatment that suited him best consisted of occasional leeching and blistering affected side, mild purgatives chiefly saline, and saline diuretics with digitalis and a gentle narcotic. He could not bear strong depletion of any kind.

In the last attack, in addition to the symptoms above mentioned, there was jaundice, orthopnœa, enormous œdema of the legs and thighs with phlyctenæ; dullness of præcordium much extended,

with great enlargement of liver, forming a hard projecting tumor in epigastrium; impulse of heart felt considerably to right of sternum as though it shook the liver, and was connected with it; severe pain along edge of cartilages of left side, and extending downwards towards umbilicus, so that he could neither bend nor straighten himself, nor lie down, but he rested chiefly leaning forward over the back of a chair for the last month. Pulse almost imperceptible. He was sensible to the last.

Section cadaveris 22 hours p.m. — Countenance placid: jaundice, great œdema of lower limbs, with ecchymoses where phlyctenæ had been. Ossification of cartilage of fourth ribs. Lungs not much collapsed; on opening lungs, anterior portions emphysematous and cottony, and lower front portion of upper lobe of the left lung drawn out in a broad flat strip like a dog's ear in front of the heart, which occupied the front of the chest, pushing the mediastinum far to the right. The left lung was generally adherent to the pleura both by old and more recent adhesions, and the lower lobe was much compressed by the heart, and œdematous, giving out a bloody, frothy fluid when cut into. The right lung had no adhesions; both lungs contained much black matter with congestion of the depending portions, but there was no effusion of serum in either pleura. Bronchial membrane deep red. Heart enormously enlarged, and all its cavities and the great vessels on both sides gorged with black coagula. Its size and weight were fully three times as great as natural; every part, including the aorta and pulmonary vessels, was dilated, but without thickening of the walls or insufficiency of the valves, except the mitral, which I unfortunately omitted to examine with care. Some atheromatous deposits in the coronary arteries, but not of sufficient extent to interfere with their circulation. No serum in the pericardium, which adhered to the heart in two points near the apex of the left ventricle; and here the surface of the heart seemed more vascular than elsewhere for the space of a penny-piece round the adhesions.

The liver was enlarged, hardened, projecting across the epigastrium, of nutmeg character, and its lobes bound together by slight adhesions. Gall-bladder full of green bile. Spleen

rather enlarged, firm, and its surface dotted over with cartilaginous deposits. Kidnies enlarged, but presenting no other unusual appearance than minute red granules (probably congested Malpighian glandules) interspersed through the cortical portion. The stomach and intestines were not examined.

OBSERVATIONS.—The chief point of interest in this case was the persistence of the moist crepitation, confined to the base of the left lung, both during the acute attacks of pain, fever, &c. and during the intervals of comparative health; and in talking over the case with a distinguished auscultator, I ventured to suggest that there might be local œdema of that portion of the lung; but his idea was that the crepitation was the result of chronic inflammation of the lung. Of this, however, there were no traces found; and as œdema did exist after death, I am induced to believe that it was produced during life by pressure of the dilated heart preventing the return of the blood from the lowest portion of the lung, which was also bound down by numerous strong adhesions. The same cause doubtless, condensed the band of lung that stretched from the upper lobe, in front of the heart. If this notion be correct, this is the first instance of local œdema of one lung that I have been able to meet with, either observed by myself, or recorded by others. The jogging impulse of the heart, imperceptible, or at least intermitting at the wrist, with bellows murmur over the mitral valve, may, I think, be accounted for by the dilated left ventricle being unable to empty itself at one contraction, at the same time that the stream of blood was divided between the aorta and the patent mitral valve, producing a sound of regurgitation through the latter, and not being able to propel the column of blood in the dilated aorta with sufficient force to produce a pulse at the wrist. This view will also explain the greater weakness of the pulse during an asthmatic attack, for the bronchial and vesicular membranes being obstructed and less fitted at this time for their function of oxygenation, a greater supply of blood would be required from the heart in the right side, while that returned from the lungs to the left side would be deteriorated in

character, and therefore unfit to maintain in their ordinary vigour the muscular fibres of the heart, by the stimulus of arterial blood. This enfeebled state of the left ventricle will also explain why the aorta and left side of the heart were distended with blood as black as that in the *venæ cavæ*.

OBSERVATIONS

ON THE

STRUCTURE OF THE CORPUS LUTEUM, AND ITS VALUE AS A TEST OF EARLY PREGNANCY.

BY ROBERT LEE, M.D., F.R.S.

(*For the London Medical Gazette.*)

FROM the dissection of five human corpora lutea, after recent impregnation, and from an examination of all the preparations of human corpora lutea in the Hunterian Museum of the College of Surgeons, I concluded that the corpus luteum "is neither produced by a thickening of the inner layer of the Graafian vesicle, nor by a deposit of a new substance between its coats, but that it is formed around the outer surface of both these coats of the Graafian vesicle, and that the stroma of the ovarium is in immediate contact with the external surface of the yellow matter."

Before the paper containing this conclusion was presented to the Royal Medical and Chirurgical Society, these five corpora lutea, resulting from impregnation, were often examined by Sir Astley Cooper, Mr. Wharton Jones, and other distinguished anatomists, who were all satisfied that both layers of the Graafian vesicle were within the yellow matter, and that this had no membranous layer, or any thing else, interposed between it and the stroma of the ovary. Dr. Todd, who was appointed by the Society to examine the preparations and drawings which accompanied the paper, came to the same conclusion. Sir Astley Cooper took a great interest in this subject, and after much investigation, said there was no fact in anatomy more completely demonstrated.

Soon after the publication of this paper on the structure of the corpus luteum, in the 22d volume of the *Medico-Chirurgical Transactions*, 1839, there appeared in the 53d volume of

the Edinburgh Medical and Surgical Journal, January 1840, Observations on Corpora Lutea, by Robert Paterson, M.D., in which the following statement was made:—"Professor Baer, of Königsberg, believes that the corpus luteum is nothing more than the internal membrane of the Graafian vesicle in a state of hypertrophy. This opinion, from the celebrity of its author, has been extensively adopted by the profession. The other view, which has been lately advanced by Dr. Lee, of London, is that the substance of the corpus luteum is deposited external to both layers of the Graafian vesicle, and consequently between it and the proper substance of the ovary. This opinion Dr. Lee has been led to advance, from having noticed in *one or two* early cases that he could divide the thick internal lining of the corpus luteum into two layers, while the external covering of it appeared to be simply the condensed cellular tissue of the ovary*." Before the appearance of Dr. Lee's paper, I had frequent opportunities of observing that the proper substance of the corpus luteum was covered by two membranes; first, by its cellular envelope, a continuation of the proper cellular tissue of the ovary; and, secondly, by an immediately investing thick and distinct membrane. Since then, however, I have paid additional attention to this subject, and have had much pleasure in demonstrating both these layers to Dr. Simpson, and a number of professional friends, as well as to the members of the Anatomical Society of the town. Any one may satisfy himself of this by a very simple experiment. Let him procure the ovary of a cow containing the corpus luteum. In this animal the parts are so large as to be easily distinguished. An incision is to be carefully made through the peritoneum and proper tissue of the ovary, and then turning their edges aside no difficulty will be experienced in turning out the corpus luteum from the ovary. On examining it we find that it is still covered with its cellular envelope. Upon cutting gently through this, and reflecting it, we find that the orange-coloured corpus luteum is still covered by a proper tunic, and when

this is cut through, and elevated with the forceps, the naked corpus luteum comes immediately into view. Now what else can this second tunic be but the external membrane of the Graafian vesicle? This arrangement may be demonstrated not in the cow alone, for it is easily to be seen in the sheep and pig, as well as the human subject. We cannot understand how Dr. Lee has fallen into this error, unless it be from the circumstance of not having examined the state of parts in the lower animals, where, as in the cow, they are exceedingly manifest."

Before the publication of my paper in the Medico-Chirurgical Transactions, I had examined the corpus luteum of the cow and sheep, and had ascertained that it is not covered by two membranes, but is likewise in immediate contact with the stroma of the ovary.

Dr. Paterson says, he "had many opportunities of observing that the proper substance of the corpus luteum was covered by two membranes," but his paper contains a reference only to five recent human corpora lutea, and in three out of these five there was no ovum found within the uterus to prove that impregnation had ever taken place, and that they were true corpora lutea, in the ordinary sense of the term. Dr. Paterson merely presumed that they were corpora lutea resulting from impregnation, and stated that they were so without furnishing proof. On what evidence his presumption rested that they were corpora lutea resulting from pregnancy, the following singular history will shew:—

"A lampighter, residing in the Canonsgate, was indicted for the murder of his wife. It appeared that the parties had been married eight years, and had had no family. The man was a sober and decent person, while the woman was addicted to the use of spirits. Latterly she had become acquainted with a young man, whose frequent visits to her in the absence of her husband excited suspicion against them. This man, in a fit of passion and jealousy, inflicted on her head wounds which proved fatal. The uterine organs were removed at the inspection, and examined afterwards. The right ovary presented externally an enlargement of the size of an ordinary marble, of a dark purple colour, having several mi-

* The number of corpora lutea referred to and described by me in the paper, was five, and in all there was an ovum in the uterus or fallopian tube. Dr. P. reduces their number to one or two.

nute vessels ramifying on its surface; a distinct depression in its centre, and the appearance of a minute cicatrix. On cutting into it, the structure and appearance of a very early corpus luteum was observed, which was formerly described. The uterus contained an extremely soft decidual membrane, *but no ovum* could be detected, although minutely and carefully examined. Indeed, although this person had conceived, there can be little doubt, from the puckered and contracted appearance of the fimbriated extremities of the fallopian tube, which would hardly admit of a small probe to enter, that no ovum could have passed into them. In this case it is possible that the woman had conceived by her husband; but it is more probable that she had not, and that the husband had great cause of provocation.* But let us suppose," adds Dr. P., "that the husband had been absent for a month or so, and had inflicted similar blows on his return. it would have become a question of the greatest importance to have determined not only if that was a true corpus luteum, but whether or not it was possible to have been produced—the result of a conception before his departure. Although this case is in so far imaginary, yet the circumstances supposed are very likely to have happened, and the appearances observed in the ovary, if carefully examined, would either have been set down, on the one hand, as a clot of blood, or as bearing at least none of the marks of the corpus luteum, as described by authors."

The following description is given of this body by Dr. P. :—

"Upon making a section of this corpus luteum, blood exuded abundantly from the whole cut surface of the ovary. This blood having been gently removed, it presented very nearly the appearance seen in fig. 2. The cellular tissue of the immediately surrounding portion of the ovary was very much filled with blood, and the external margin of the corpus luteum was of an intensely dark colour; thicker, however, on one side than the other. The internal membrane, which was of a bluish colour, and partly filled with blood, was irregular in its shape; and between it and the dark external margin, formerly mentioned, the substance was of a brighter red colour, having dark striæ

or folds running through it. After immersion in spirits, these striæ assumed a yellow colour, and the internal membrane could, with delicacy, be raised up from the substance of the corpus luteum. The uterus of this case was a little enlarged, and contained an extremely thin and soft decidual membrane*."

From the preceding history and description, and coloured representation of this body in the ovary in a recent state, I was led to conclude that it was nothing but a coagulum of blood, such as I have seen in a multitude of cases where impregnation had never taken place, nor any suspicion of pregnancy been entertained. I had never observed a corpus luteum, in the earliest stage, undoubtedly resulting from impregnation, so completely resemble a mass of coagulated blood in the ovary. To call this a true "corpus luteum," or one resulting from pregnancy, seemed unwarranted. In all the true corpora lutea in my possession, the convoluted yellow matter was seen outside the two layers of the Graafian vesicle, interspersed with radiating bands; but nothing of this appeared from Dr. P.'s delineation, but the appearance of a clot of blood, with a layer of lymph or fibrine in the centre. These circumstances, conjoined with the following striking facts, viz. the appearance of a single layer, alleged to be the internal layer of the Graafian vesicle, in the interior, whilst there was said to be a proper capsule outside,—no ovum found within the uterus,—and the still more striking fact mentioned by Dr. P., that the fallopian tube was so contracted "that no ovum could have passed into it," fully justified me in drawing the conclusion, that this *red body* in the ovary was not the result of impregnation, and was *neither* a true nor a false corpus luteum, but a clot of blood.

With this conviction, I stated in my fifth lecture that I believed this to be a false corpus luteum (the term corpus rubrum would have been more correct), and made the following remarks upon it in a paper On the Value of the Corpus Luteum and Deciduous Membrane as Tests of Early Pregnancy, published in the MEDICAL GAZETTE, December 12, 1842:—"It is inferred from this sin-

* The preparation is stated by Dr. P. to belong to Dr. Simpson, to whom he expresses his obligations for allowing him to examine it.

gular history, although no ovum, nor any vestige of an ovum, could be detected on the most minute and careful examination, neither embryo, vesicula umbilicalis, amnion nor chorion, that this murdered woman was pregnant, and that she was an adultress. Not only is the pregnancy considered a fact of absolute certainty, but the red clot of blood in the ovary, which does not present one of the characters of a true corpus luteum—into the composition of which there does not enter a particle of yellow matter—is described as a corpus luteum ‘a very short time after the rupture of the Graafian vesicle and escape of the ovule.’ An ovule which was never seen is presumed to have escaped from this ovary; but on dissection, though hunted out with the greatest care, it was nowhere to be found. My conscientious belief is, that a *fecundated ovum* never existed here at all, and that this woman, who had lived eight years with her husband, and was barren, and whose internal uterine appendages were in a state which rendered pregnancy impossible, or at least highly improbable, died during menstruation. I have so often seen all the appearances here described in the ovaria and uterus of women who have never been pregnant, that I have no doubt of the fact. If I were summoned into a court of justice, I would have no hesitation in declaring upon oath, from the evidence furnished, that the proofs of pregnancy were wholly wanting. With this deep conviction upon my mind, I could not avoid drawing the attention of my class to this case, and imploring them to be cautious how they gave evidence in courts of law to criminate unmarried women who have committed suicide, or died suddenly from any cause.”

“But,” says Dr. P., “the uterus of this case (woman?) was a little enlarged, and contained an extremely thin and soft decidual membrane. The utter worthlessness of the decidua as a test of pregnancy found in the uterus of this case (!) will easily be estimated from the following quotation from Dr. Blondell’s Lectures, and also the real value of the microscopical researches determined which have led to the revival of an antiquated and exploded error, viz. that the decidua is nothing but the altered mucous membrane of

the uterus.” The decidua is sometimes produced in cases of difficult menstruation; and it is important to remember that it may be mistaken for abortion. It resembles it in the pains, discharge of blood, &c. But the one presents an embryo, at various stages of increase, while in the other that is altogether wanting. It seems now agreed that the discharge of this membrane (recognised by Dr. Baillie to be similar in structure to the decidua) occurs frequently in unmarried females. It would appear to be generated spontaneously by the inner membrane lining the uterus.”

It was observed at the commencement of this paper, that “If from conviction I could alter my opinion on Dr. Paterson’s corpora lutea it would afford me the greatest satisfaction to do so; for I know from experience that the pleasure of renouncing an error is only equalled by the delight felt on discovering a new truth.” No opportunity, however, was ever offered me of arriving at this conviction.

Dr. Paterson considered these criticisms unjust, and as calculated to put an “incubus,” as he says, upon his character as an observer. Nearly two years after they had been published, he “resolved, by the advice of some professional friends (whose names are not mentioned), to submit the preparation to my inspection.” “My friend, Dr. Bowman, of Sunderland,” he says, “submitted it to you, not suspecting it was the identical specimen so much discussed.” It will be seen by the following letter that all the facts of the case were carefully concealed, in order that I might arrive the more certainly at a correct conclusion, and avoid the danger of error! To render the opinion which I was to give of the greatest weight, the preparation was wrapped up in linen rags, having the appearance, from their colour and smell, of having recently been employed at a post-mortem examination at Monkwearmouth! Nothing was said about the murder of the woman, of the decidua in the uterus, of the contracted tube, of the bright red colour of the mass in the ovary, and the blood which escaped in profusion when it was opened, nor of the four years the preparation had been in alcohol. It was not considered necessary for the re-

moval of the "incubus" on Dr. Paterson's "character as an observer" that any of these facts should be revealed.

Monkwearmouth, May 9, 1844.

Dear sir,—I venture to encroach on your valuable time, to ask your opinion of the accompanying preparation illustrative of a point to which the medical world knows you to have paid much attention.

Is the corpus luteum in this case a true or false one? It was taken from the body of a female upwards of thirty years of age. She died suddenly, and no accurate information could be gained regarding her last menstrual periods. Several medical gentlemen have examined the corpus luteum, and are so much divided in opinion about it, that they would feel deeply indebted to you to examine it, and favour us with your *decision* upon the question.

I hope you will have the goodness to excuse the great liberty a stranger thus ventures to take; but knowing your kindness, and having every confidence in your opinion, I have the honour to remain, your obedient servant,

HENRY O. BOWMAN, M.D.

Dr. Lee.

P.S.—As the preparation belongs to a medical friend, who was so kind as to allow me to examine it, I shall feel obliged by your returning it with your decision. If it were mine you would be heartily welcome to it; indeed I should have considered it my duty to have presented it to you.—H. O. B.

The following was the condition of the uterus and its appendages when they came to me:—

The uterus was not enlarged in the slightest degree beyond the ordinary size at the middle period of life in women who have never been pregnant. Its walls were compact, and the strata of muscular fibres could not be separated from one another as they always can be after recent impregnation. The lining membrane of the uterus was unusually thickened, but no part of it was covered with deciduous membrane. Under alcohol and water, with the naked eye and with the magnifier, I could not detect the slightest portion of this membrane adhering to the inner surface of the uterus, nor did the lining membrane of the organ present the appearance which it usually does when the recent decidua has been removed with the utmost care. The glands of the orifice and cervix uteri were not developed, and there was no change in

the walls, cavity, cervix, or orifice of the uterus, to indicate that recent impregnation had taken place. If, therefore, as Dr. Paterson states, "the uterus of this case was a little enlarged, and contained an extremely thin and soft decidual membrane" when first opened, the enlargement had entirely disappeared, and the thin and soft decidual membrane completely vanished, when the uterus came into my possession. Why "no ovum could be detected, though minutely and carefully examined, was now fully explained."

The *fimbriated extremity of the right fallopian tube* had adhered throughout nearly its whole extent by old, dense, false membranes, so as to fix the tube immoveably in its unnatural position, and render it incapable of performing its functions. Neither spermatic fluid could have passed from the uterus to the ovarium, nor could an ovum have been transmitted from the ovarium to the uterus. These firm false membranes had been extensively divided artificially, but by placing the cut ends in apposition, it was obvious that the corpus fimbriatum had been extensively, if not completely, adherent to the ovary, and that the tube must have been impervious. The condition of the tube and ovarium, therefore, fully confirmed the accuracy of Dr. P. when he stated, "that from the puckered and contracted appearance of the fimbriated extremity of the fallopian tube, which could hardly admit of a small probe to enter, that no ovum could have passed into the uterus." But, though "no ovum could have passed into the uterus," he nevertheless maintained "that this person had conceived."

A section had been made, as Mr. Wharton Jones describes, dividing the ovary and the body it contained into two similar halves. The appearance which this section of the body presented was like that of a firm dark clot of blood, having in its centre an elongated membraniform shred, one end directed towards the interior of the ovary, the other towards the exterior. From this shred, which was smooth on its free surface, processes extended here and there in a radiating manner into the substance of the clot-like body. The body in question was of a lenticular form, about six-tenths of an inch in diameter, and about four-tenths thick,

and projected on the surface of the ovary by somewhat more than half its diameter. The prominent part being covered only by the indusium of the ovary, the dark-red brown colour of the body shone through.

As Mr. Jones has further stated, I was disposed to consider the body in the ovary to be what to the naked eye its general appearance seemed to indicate, viz. a clot of blood containing a flake of fibrine, from which the red corpuscles had been separated. And on making a fresh section of one of the halves of the body in the same plane as the first, my belief was strengthened that it was not a corpus luteum resulting from impregnation; for the appearance which presented itself was such, that the naked eye could not well recognise it to be any other than that of a clot of blood. The extraordinary manner in which this body projected beyond the surface of the ovarium was the first circumstance that attracted my attention on examining it, and satisfied me that, although it had a yellowish colour, it was a false corpus luteum, and wholly unconnected with pregnancy. In no true corpus luteum resulting from impregnation had I ever witnessed this remarkable projection; but in several false corpora lutea in the Museum of St. George's Hospital it is so obvious that it immediately attracts attention. The appearance of the membrane in the centre of the clot was also widely different from the appearance presented by the empty Graafian vesicle within the yellow matter in all the early corpora lutea resulting from pregnancy which had ever come under my observation. The absence of the decidua within the uterus, the morbid condition of the fallopian tube, the unusual projection of the body in the ovary, the colour both of the old and fresh sections of it, which presented nothing but the appearance of a clot of blood, were the circumstances that led me to conclude, though totally ignorant of the history of the case at the time, that it was a false corpus luteum, and did not result from pregnancy. This opinion I expressed to Mr. Wharton Jones in the clearest possible manner before he commenced the microscopical examination of the body in the ovary, and during the investigation.

Mr. Jones thought that no conclusion should be come to, considering the

gravity of a decision on such a point, until the body had been subjected to a most careful microscopical examination, without which, indeed, he believed any decision would be mere guess work; coinciding in the propriety of this, I gave over to him one half of the ovary and the body in it for microscopical examination. Had I been aware that the preparation had been four years in alcohol I should not have permitted an appeal to be made to the microscope at all, knowing how little trust Mr. Jones puts in results obtained under such circumstances. I would have decided with the naked eye that it was a mere clot of blood in the ovary, and not a corpus luteum resulting from pregnancy, and on communicating this decision to the stranger at Monkwearmouth, would never have discovered the treacherous purpose for which he had sent it to me. The incubus would have lain on Dr. Paterson's character neither heavier nor lighter than before, and the ridiculous conspiracy into which he and his friends had entered would never have been revealed.

"Examined microscopically," says Mr. Jones, "the central membranous shred was found to present the following structure:—

"1. On its free surface a fine film of tessellated epithelium. 2. Invested by this epithelium was a stratum of finely interwoven transparent fibres, with dark contours, somewhat like elastic tissue. 3. Outside all was a layer identical in structure with the stroma of the ovary; the same structure as that composing the principal thickness of the walls of Graafian follicles."

"The membranous processes possessed a similar structure, and were found to be continuous with the stroma of the ovary. That part of the body next the substance of the ovary had, by its pressure, so condensed the stroma at the place, that the latter looked somewhat like an external capsule sending processes inwards, which met and interwove with those sent outward by the central membranous shred. But that the appearance of external capsule was the result simply of matting of the stroma of the ovary by pressure, is shown by the circumstance that it was absent at the peripheral part of the clot-like body, there being there, as already said, merely the indusium.

"As to the microscopical characters

of the clot-like matter itself:—this was found to consist of granulous corpuscles, somewhat like so-called compound inflammation globules closely aggregated, and red blood corpuscles interspersed amongst them. The latter had lost some of their colouring matter, but the granulous corpuscles were tinged red, as if they had imbibed it.

"The conclusion which is to be drawn as to the nature of the body from this investigation is, that it is a true corpus luteum in an early stage; that the central membranous shred is the wall of the Graafian follicle, from which the ovum had escaped; and that the clot-like mass (which would have by and by acquired the characteristic yellow appearance of the corpus luteum, traces of which, indeed, could in some deep places be detected), together with the membranous processes extending through it from the central shred to the stroma of the ovary, is the stroma surrounding the Graafian follicle infiltrated with bloody-looking matter.

"I say *bloody-looking*, for although it is certain that there is some blood present, it remains a question what sort of matter the granulous corpuscles were developed from—blood effused in substance, or exuded lymph?"

Here it is evident Mr. Jones employs the term true corpus luteum from a consideration of its anatomical structure alone, not venturing to decide positively on the nature of its relation to conception.

"According to this view," adds Mr. Jones, "the formation of a corpus luteum would be quite independent of the contact of seminal fluid with the ovary or ovum, and consequently independent of impregnation. And that it is so has been already established, as regards the lower animals, by the experiments of Haighton and Blundell on rabbits, viz. that though by obliteration of some part of the female genital passages, the access of semen to the ovary was prevented, still Graafian follicles were observed to have burst, and corpora lutea formed *post coitum*.

"The same circumstance appears likely to have held in the case of the woman whose ovary forms the subject of the preceding observations, for Dr. Lee informs me that the fallopian tube of the same side was diseased and contracted, if not obliterated, and that

the uterus had undergone none of the changes usually observed in its cavity and cervix after recent impregnation."

On the microscopic evidence thus furnished to me by Mr. Jones, and upon that alone, in opposition to the opinion I had formed with the naked eye, I admitted that this body in the ovary was a true corpus luteum; but the term was employed by me in the sense in which it is understood by Mr. Jones, and as furnishing no proof of impregnation. I never for a moment contemplated going to the Medico-Chirurgical Society and describing this body as a true corpus luteum resulting from impregnation. Had I not been most happily prevented by want of time, the whole truth now stated would have been communicated to the Society, and it would never have been discovered that the ovary belonged to the lamp-lighter's wife.

And that the same view regarding the nature of the body in the ovary as that which I originally took will still be taken by the greatest anatomists, appears certain from the following opinion given of it by Professor Owen on the 7th of August last:—"Independent of any history connected with it," said Mr. Owen, in the most positive and unhesitating manner, after a careful examination, "I would give the opinion that it is a false corpus luteum. It would formerly have been stated to be a true corpus luteum, and affording undoubted evidence of pregnancy; but I do not think that any person conversant with the structure of corpora lutea resulting from pregnancy would regard this as a normal specimen of that structure. I should never have thought of giving a decided opinion of impregnation having taken place from the presence of this extravasated blood in the ovary around an ovisac." Professor Owen's opinion, therefore, coincides with that originally given by me, and may be considered as settling the point in dispute.

If I were now summoned into a court of justice, I would have no hesitation in declaring upon oath, from the evidence furnished, that the proofs of pregnancy were here wholly wanting.

I would now willingly take leave of this subject, feeling that enough has been done to establish the truth, but there are other circumstances connected with the affair which it becomes abso-

lutely necessary for Drs. Paterson and Bowman to explain to the satisfaction of their professional brethren. Three letters were sent by me to Dr. Bowman respecting the preparation in question, but no copies of these were kept by me. The first of these letters, I recollected distinctly, was written about the middle of May, 1844, the second about the 20th May, and the third near the end of June. The second and third of these letters were duly acknowledged to have been received by Dr. Bowman, but no acknowledgment was given by him that the first letter had ever reached Monkwearmouth. This circumstance was remarked at the time, but it raised no suspicion that anything wrong was intended, or that the fact would be questioned that such a letter had been sent. All these letters Dr. Bowman positively affirms were sent forward to Dr. Paterson, and they were all consequently in his possession when he wrote to me as follows on the 26th July:—"Under these circumstances, I resolved, by the advice of some professional friends, to submit to your inspection the preparation of the disputed corpus luteum itself. My friend Dr. Bowman, of Sunderland, submitted it to you, not suspecting that it was the identical specimen so much discussed. You have declared to Dr. Bowman, in two letters which I have now before me, that the body which had not one of the characters of a true corpus luteum is really a true corpus luteum in an early stage." In reply to this, I stated that I had not preserved copies of my letters to Dr. Bowman, and requested Dr. P. to send copies of them to me. On the 2d August this request was complied with, but in an imperfect manner, the second and third being sent, but the first not. The second bore the date of May 22d, the third of June 26th. My first letter to Dr. Bowman, which had been written previous to the 22d of May, continued to be unacknowledged. Dr. Paterson made no mention of it whatever, though I considered it absolutely impossible for the opinion given by me in the second letter to be understood at all without the first. No time was lost by me in writing to Dr. Bowman for information respecting the three letters I had sent to him, but the only circumstance he could recollect about them was that

they were all in Dr. Paterson's possession.

Monkwearmouth, 6th August.

My dear sir,—As soon as I received your letter, I wrote to my friend Dr. Paterson, who *had your letters in his possession*, to furnish you with copies of them as you requested, which, from a letter I received yesterday, I hear he has complied with. This is my apology for not having acknowledged your letter ere this.

I take this opportunity of assuring you that I was totally ignorant till some time after I had forwarded the preparation to you, that this was the corpus luteum about which you and Dr. Paterson had differed in opinion.

The trouble you have taken and the kindness you have shown in complying with my request, place me under an obligation which it will be my study at the first opportunity to repay.—I remain, your obedient servant,

H. O. BOWMAN.

Dr. Lee.

Monkwearmouth, 7th August.

My dear sir,—In reply to your letter I received this morning, I beg to inform you that my friend Dr. Paterson has *all your letters at present*, and I do not recollect their dates; but should you desire it, I will apply to him for the information you request.

I remain, ever yours,

Dr. Lee.

H. O. BOWMAN.

Finding that Dr. Bowman did not furnish me with the dates of my letters, I wrote to endeavour to ascertain their number; but his answer in regard to this point also supplied me with no information. He affirmed, however, again positively that they were all in Dr. Paterson's possession.

4, Saville Row, 8th August, 1844.

My dear sir,—I have again to request that you will, by return of post, inform me whether you did not receive from me more than *two* letters relating to the preparation in question. The dates are of no importance, but it is of the greatest that I should receive a positive answer to my simple question. You cannot fail to remember the number of my letters.—I remain, dear sir, very faithfully yours,

ROBERT LEE.

Monkwearmouth, 9th August, 1844.

My dear sir,—I cannot at present give you an answer to your question, as *Dr. Paterson has all your letters referring to the preparation in his possession, and my memory will not allow me to speak positively*. I will write again to Dr. P., and will be able, in the course of a day or two, to give you a

positive answer.—I remain, dear sir, your obedient servant,

H. O. BOWMAN.

Dr. Lee.

The following letter was addressed to Dr. Paterson on the 5th August.

London, 4, Saville Row,
5th August, 1844.

Dear sir,—I wrote another letter to Dr. Bowman, before the 22d May, 1844, of which you have not forwarded a copy to me. I am much obliged to you for the copies of the *two* you have sent, and I trust you will feel entirely satisfied with the account which Mr. Wharton Jones will give in the next number of the Medical Gazette of his microscopic examination of the body in question.—I remain, dear sir, very faithfully yours,

ROBERT LEE.

To Dr. Paterson.

Leith, 10th August, 1844.

Dear sir,—I beg to acknowledge the receipt of your letter dated August 5th, which would have been replied to sooner, had it not been that I expected, ere this, to have heard from Dr. Bowman in answer to a letter sent to him immediately after the receipt of yours. You *accuse* me of having kept a letter which you wrote to Dr. Bowman, of a previous date to those copies of which were sent to you. In reply to this *accusation*, I have to state that I never received any letter of yours from Dr. Bowman of a prior date to those the copies of which were sent you. In addition, you make no reference to a previous letter in the first one I received of the 22d May, and I am convinced, that, had any previous letter arrived, such would have been immediately communicated to me by Dr. Bowman. As soon, however, as I receive an answer from Dr. B. I will write to you.

I shall be glad if Mr. Jones's statement of the question in dispute between us shall be satisfactory to me.—I have the honour to remain, your obedient servant,

ROBERT PATERSON.

Dr. Robert Lee, London.

On receiving this letter I resolved to have no further correspondence with its author, and stated this to him.

The following letter has been published by Dr. Paterson in the last number of the Edinburgh Medical and Surgical Journal, No. 9, in the correspondence said to have taken place with Dr. Lee. This letter was never sent to me (at least no such letter was ever received by me), but the date and other circumstances prove that it is a spurious edition of the last letter, and it shows how Dr. Paterson was

actually employed at the time in raising up an insinuation of his own, into an accusation against himself, which had never been made by me. The reader will see that there was no insinuation or accusation made in my letter of the 5th August against Dr. P., nor did I suppose, at this time, that there existed an individual in the medical profession, or any other profession in Great Britain, so base and unprincipled as to attempt to suppress a letter in a scientific correspondence for the purpose of convicting another of a gross contradiction against himself.

Leith, 9th August, 1844.

Dear sir,—I beg to acknowledge the receipt of yours of the 5th instant, which would have been answered sooner, but that I have been waiting for a reply to a letter sent to Dr. Bowman, for the purpose of ascertaining whether or not there was a previous letter to those, copies of which were sent to you. I was astonished to observe your *insinuation* that I had kept back a letter which you wrote to Dr. Bowman, of a previous date to those copies of which were sent you. In reply to this accusation, I may state, that I never received any letter which you had communicated to Dr. Bowman prior to the date of those the copies of which were sent you. In addition to this, however, in your letter of the 22d May, you refer to no prior communication to Dr. B. which I think under the circumstances, would have been referred to. I am equally convinced that Dr. Bowman did not receive any previous letter, otherwise it would have been forwarded to me. I am sorry that I have not heard from Dr. Bowman before this time, for it has delayed my reply to your last letter longer than I intended.

I shall be glad if Mr. Jones's statement of the question in dispute between us shall be satisfactory to me.—I remain, your most obedient servant,

(Signed) ROBERT PATERSON.

Dr. Robert Lee.

Dr. Bowman, whose memory, on the 9th of August, would not allow him to speak positively about the number of letters he had received from me, would appear to have had this faculty restored to him in a miraculous manner the following day, for he then distinctly recollected their number and their dates, as is shown by the subjoined letter from Dr. Paterson. In this letter Dr. P. now acknowledges the existence of the letter from me to Dr. Bowman which he had previously denied, and

complained of my accusing him of suppressing it.

Leith, 12th August, 1844.

Dear sir,—I presume that you will by this time have heard from Dr. Bowman himself regarding the number of your letters to him. I may state, however, that they were three in number. The *first*, dated May 13, acknowledges your receipt of the preparation; the *second*, dated May 22, contains your opinions regarding it; and the *third*, dated June 26, accompanies the return of it. These, Dr. Bowman distinctly states, were the only letters received from you in connexion with the preparation sent you.

I have just seen Mr. Jones's description of the preparation, and more especially of the corpus luteum in question, in the *Gazette* of Saturday last. It contains one or two most important errors which it will be necessary to have corrected. Before doing so, however, I am anxious to know if Mr. Jones's letter contains all the statements you propose to make public regarding your unjust criticisms on the case, and as more especially stated by me in a former letter?

I should feel obliged by your communicating to me, with your earliest convenience, if any further statement on the subject is to be made public.—I have the honour to remain, your obedient servant,

ROB. PATERSON.

Dr. Robert Lee, London.

This acknowledgment of the receipt of my first letter of the 13th May, was not, however, accompanied with a copy of this letter. It was still withheld, and is now withheld, for no duly-authenticated copy of this letter has yet reached me; nor have any authenticated copies of the second and third yet been obtained, though I have applied to the proper quarter for these. Considering the inaccuracy of the published copies of the letters Dr. P. sent me, no dependence can be placed upon the accuracy of the copies he has published of those I sent to Dr. Bowman.

W. J. Dodd, Esq. of Monkwearmouth, called upon Dr. Bowman, at my request, to demand an explanation of his conduct in this affair, and to inform him that until he revealed the whole of the circumstances I would consider him to have acted throughout with anything but professional honour and honesty. Mr. Dodd informed Dr. B. that I would not free him from knowing collusion in the transaction unless he wrote a full and satisfactory account of his share in it. He told Mr. Dodd that he was to be away from home for

a day or two, but that on his return he would write to me. Fourteen days elapsed, but Dr. Bowman remained silent, and insensible to the accusations personally made against him by Mr. Dodd. With the view of once more testing the retentiveness of his memory, and obtaining a more full development of his character, I addressed him as follows on the 24th of August, with the desired effect:—"You have now had abundance of time to refresh your memory, and can tell me, no doubt, every thing respecting the first letter I wrote to you, and whether it was impounded at Monkwearmouth, or actually sent forward, with the others, to Leith, as you stated in a former letter. Your friend in the north threatens to publish the correspondence between you and me. I hope you will take care, before he does so, that my first letter is forthcoming, and that it is published with the others. Truth has nothing to fear. A man who conscientiously tells the truth has only to go on in his course; but a man who departs from the truth has everything to dread. Mr. Dodd will again soon call upon you to receive from you those explanations which are evidently required to clear your character from the suspicions under which it must lie until you reveal all the circumstances connected with this affair. Your first letter to me led me to form a very favourable opinion of your candour and integrity: I pray that my good opinion of you may continue unchanged."

After receiving this letter, Dr. Bowman went to his old and intimate friend and associate, Dr. Paterson, of Leith, where not only his memory, but all his other intellectual and moral faculties, appear to have become bewildered. Once more it will be seen, in the following letter, that he denies the existence of my first letter of the 13th May, which he distinctly stated to Dr. Paterson on the 12th August had been received by him, and which he had before thrice affirmed was in Dr. Paterson's possession. It will be further observed, that Dr. Bowman suggests the propriety of my forging a letter to supply the place of my first letter, which, in his loss of memory, he wished to annihilate, but which was at the time in Dr. Paterson's possession. In his state of

bewilderment, Dr. Bowman steps boldly forward to give an implicit denial to an insinuation that another letter was received by him than those that had been acknowledged. The insinuation is contained in no letter written by me; it is made by Dr. Bowman himself, like the insinuation and accusation justly made by Dr. Paterson against *himself*. It is made by Dr. Bowman obviously for the purpose of perverting the truth, and causing it to be believed that I claimed from him the restitution of a fourth letter, which had no existence. In the Edinb. Med. and Surg. Journal, Dr. Paterson has followed the same course, for a similar purpose—misleading the reader who is unacquainted with the facts. Dr. Paterson says, Dr. Lee “declares that there was another letter to Dr. Bowman (the gentleman who sent the preparation for me) more than those the copies of which I transmitted to him.” I repeat the declaration, that no copy of my first letter was sent to me by Dr. Paterson at the time its existence was acknowledged both by him and Dr. Bowman, and, therefore, that there was another letter more than those the copies of which were transmitted to me. The acknowledgment was made, but the letter was still withheld.

Leith, 27th August.

Sir,—Your letter of the 24th August, through Mr. Dodd, has already been duly acknowledged, and I have now again to state that no refreshing of my memory can ever make me produce a letter which had no existence. You are already in possession of the dates and general import of all the letters I received, and Dr. Paterson has transmitted copies of them. I now give an implicit denial to your insinuation that another letter was received than those that have been acknowledged. The *onus probandi* therefore lies with you. Probably you will be able to concoct a letter for the purpose, and to favour me with a copy of it, and add an additional eulogium on *truth*?

The freedom of access which I at once gained to you, and your obliging letters to me, a stranger, gave me a favourable opinion of your goodness. Your last discourteous letter, however, has dissipated all such ideas, and renders it necessary for me to refuse all further correspondence with you.—I have the honour to be, your obedient servant,

H. O. BOWMAN.

Dr. Lee.

To complete the portrait of H. O. Bowman, M.D., of Monkwearmouth, it

will only be necessary to add the following letter:—

Monkwearmouth, 27th May.

My dear sir,—I feel exceedingly obliged and grateful for the attention and trouble you have taken in examining and giving me your opinion of the preparation I took the liberty of forwarding to you. It is very gratifying to me that you, whose opinion bears such weight in the medical world, should have come to the same conclusion *I had already formed*, namely, that it is a true corpus luteum.

I have communicated with my friend, who will be happy to let you retain the half of the ovary as you request, but as he has some intention of publishing the case at some future period, he would wish you to return the remainder as soon as convenient.

I take this opportunity of returning you my sincere thanks for your kindness and attention.—I have the honour to be, your obedient servant,

H. O. BOWMAN.

Dr. Lee.

DR. SYNNOT'S CASE OF SUDDEN BLINDNESS.

To the Editor of the Medical Gazette.

SIR,

I SHOULD feel obliged by your inserting in your valuable journal the following brief notice of a case which I considered to be one of effusion of blood either within or around the optic nerve. I think the case presents several peculiarities; and as I have never heard of a perfectly similar one, I should much like to learn what view may be taken of it by some of your more experienced readers. I therefore refrain from offering any observations of my own.

I am, sir,

Your obedient servant,
ROBERT SYNNOT, M.D.

8, Westbourne Place, Eaton Square,
Oct. 23, 1844.

Case of sudden blindness, (produced by effusion of blood on the optic nerve?).

M. D., aged 18, a laundry-maid, of strumous appearance, came to me on the morning of the 8th of this month. The previous evening, as she was reaching up to take some clothes off a line, she experienced a sensation as if something had fallen into her left eye, followed by total and instantaneous loss of vision. There was no lachrymation nor any inflammation of the

conjunctiva; the cornea and humours perfectly clear and unclouded, so that it was evident there was no effusion of blood within the eyeball. There was slight redness of the parts surrounding the eye, probably produced by the patient's having rubbed the eye a good deal. The iris contracted and dilated actively, according as the light was more or less intense; though there was no perception whatever of light, even on holding a candle pretty close to the eye. On making an examination, I found there was no foreign body present, though she still complained of the sensation of something being in the eye. There was deep-seated pain in the orbit, and supra-orbital headache. She was ordered to take a brisk purgative, to have leeches to the temple, and afterwards to keep a cold lotion applied to the eye. She was further directed, as soon as the medicine had operated freely, to take a powder composed of Calomel, gr. i. j, Opium, gr. $\frac{1}{3}$, Tartarized Antimony, gr. $\frac{1}{4}$, which was to be repeated every second hour.

The next day a blister was applied to the temple, and the mercury continued. On the 10th the leeching was repeated, as she complained greatly of the pain in the orbit and forehead.

Mercury continued.

11th.—Mouth becoming tender.

Continued the mercury.

In the evening she could distinguish the light of a candle.

12th.—Could see pretty well; the gums sore. Stopped giving mercury.

13th.—Vision quite restored, and has continued so ever since. There was no fever at any time during this attack, and the pulse was never above 70, soft and full.

ANALYSES AND NOTICES OF BOOKS.

“L'auteur se tue à allonger ce que le lecteur se tue à abréger.”—D'ALEMBERT.

An Exposition of the Laws which relate to the Medical Profession in England; with an Appendix, containing an ample Analysis of Sir James Graham's Bill for the better Regulation of Medical Practice. By JOHN DAVIES, M.D. Hertford. 8vo. pp. 84. Churchill.

This moderate publication of Dr. Davies is well timed. The present
883.—xxxv.

agitated condition of the medical profession makes all anxious to have knowledge of the laws under which its members exist and carry on their calling; but until Dr. Davies's work appeared, we know of none except the larger and more expensive volume of Wilcox, that contained the kind of information which is so much desired at this particular moment. Dr. Davies's publication gives an account of the various charters and enactments that have reference—1st, to the College of Physicians; 2d, to the College of Surgeons; 3d, to the Society of Apothecaries; 4th, to the University of London; and it concludes with a good analysis of the Medical Bill, which is now attracting so much attention throughout the country.

Dr. Davies's view of this proposed measure is decidedly favourable; had he had a finger in the pie himself, he could not have regarded it with feelings of higher confidence, nor given it in all its parts, his more unequivocal support. The author in a private note to us, regrets that we have not taken the same view of the measure as he has himself. We give the Doctor credit for perfect candour in his mode of viewing and of discussing the measure; we greatly approve of the tone and temper, and excellent taste in which his analysis is written; it is concise and to the purpose, and we cannot pay the author a greater compliment than by requesting all *impartial* persons to procure his work and to read it, and to judge of it for themselves. They will obtain much useful information from the historical portion; and from the critical part they will, perhaps, rise with views considerably modified from those with which they sat down, supposing these views to have been unfavourable or hostile.

A Concise Historical Sketch of the Progress of Pharmacy in Great Britain, from the time of its partial separation from the practice of Medicine until the establishment of the Pharmaceutical Society. By JACOB BELL. 8vo. pp. 108.

This, too, is a publication that we believe must be acceptable to the profession at this time. There can be no doubt that *pharmacy*—and we scarcely separate *materia medica* from pharmacy in the present day—is even a very important element in the medical profes-

sion. The day was, indeed, when a knowledge of simples constituted the principal science of the physician; and when his learning extended to little more than the history of the substances with which he treated disease. But our object now is not to analyse Mr. Bell's production; it is merely to make its existence known to our readers, and to invite their attention to it as a source whence they may obtain information of a kind that is peculiarly useful at this time. We may, perchance, have to revert to it ourselves more particularly by and by.

MEDICAL GAZETTE.

Friday, November 1, 1844.

"Licet omnibus, licet etiam mihi, dignitatem
Artis Medicæ tueri; potestas modo veniendi in
publicum sit, dicendi periculum non recuso."

CICERO

A MANIFESTO

BY THE MEDICAL AND SURGICAL ASSOCIATION
OF THE BOROUGH OF MARYLEBONE.

8vo. London, Oct. 1844.

HAD our limits allowed us, we should have felt it a duty to the profession to have republished this document entire, and by way of pendent to the Manifesto of the Royal College of Physicians of Edinburgh, printed in this day's GAZETTE. It supplies us with quite a new feature in the subject of Medical Reform: the object proposed is no less than the establishment of "A College of General Practitioners in Medicine, Surgery, and Midwifery, to be incorporated by Charter and Act of Parliament, having an elective Council, a Court of Examiners, and power to frame by-laws, and to examine and license all future general practitioners."

This movement on the part of the many respectable gentlemen whose names are connected with the Marylebone Medical and Surgical Association, cannot be viewed as other than the necessary fruit of the spirit that has dictated the proposed Medical Bill, and of the line of conduct that has been

pursued by the Council of the Royal College of Surgeons towards its members. We have taken much the same view of the tendency of the Bill as the Marylebone Association; we have deplored the introduction of grades into a department of the profession that admits of none, and we have repeatedly denounced what we believe to be the injustice of arbitrarily elevating one set of men, and depressing another, both having alike started on a footing of perfect equality. The immense majority of the members of the Royal College of Surgeons ask by what act of theirs, since they entered on this footing of perfect equality with all, they have made themselves obnoxious to degradation? For they feel that it is even as much degradation to have a certain number of themselves raised arbitrarily over their heads, as it would be were they to be thrust lower, a favoured few being retained on the old level.

The Council of the College of Surgeons have the undoubted right to make what regulations they see fit, having a prospective bearing: those who present themselves, craving entrance into the College under these, having the conditions before them, will know what they have to expect; if they have only qualified for a lower grade, they will have no reason to complain that they are not placed in one that is higher; but we apprehend that, upon every principle of equity, they who have started on the same basis, who have all alike qualified for one grade, who have *all alike received a diploma of the same tenor and value, as testimony to the public of the equality of their acquirements*, should not be subjected to degradation, whether in fact or by implication. The Council of the College of Surgeons, it seems to us, cannot without an unjust and indefensible straining of its power persevere in its present

course of showing a preference to one class of its members over another. They who are members of the Royal College of Surgeons up to this hour, are so in virtue of having pursued a course of study similar in point of extent, and of having undergone an examination identical in kind and character, and paid a fee of one denomination in every instance;—all are *de jure*, as they are *de facto*, equal. What power that is not arbitrary and unjust shall make them otherwise? The attempt is against every principle recognised in English law, whether statute and common, or in equity; above all, it is against that spirit of fair play and generous usage which we Englishmen pride ourselves upon sucking in with our mother's milk, and preserving through life as that which is dearest in our character. Would not a bill filed in Chancery by one or more of those members of the Royal College of Surgeons, who believed that it was in contemplation to let them of certain privileges which either were, or had been, conferred on others of the body, upon grounds purely arbitrary, be entertained? If it were, we feel persuaded that it would carry the day against the governing body. The petitioners in such a case would have right on their side; and, in theory at least, right in England has yet been held to be might.

We own that we are totally at a loss to conceive the spirit that has prevented the Council of the Royal College of Surgeons from embracing the opportunity that was afforded them of raising the members of the College, not only in their own esteem, but also in the estimation of the public, of ennobling them in some sort, of giving to the whole profession of medicine in England, which they actually represent, a worthier position, a higher character. It is because they have not done this, however,

that we see the profession in arms from Land's End to the Tweed, and that we have proposals for Colleges of General Practitioners. The exigencies of the public have created this class of medical men; who, as a whole, and as they stand, are vastly better educated and far more skilful in the treatment of disease than were the most accomplished physicians of the last century.

These gentlemen "do well to be angry"; they have been severely treated by a knot of their own body, and they ought not to rest, and we imagine will not rest, until they have righted themselves. Let the profession of general practitioners from north to south procure the "Manifesto of the Marylebone Medical Association," and get it by heart; it is the truth; it is the right. The general practitioners want a guide in clearly understanding the position in which they and their department of the profession are placed by the Bill and the Charter; in this manifesto they will find what they require; and though all may not be of the same mind as its authors, as to the remedy, or that a "College of General Practitioners" is the best measure that can be aimed at, still the general practitioners of England must have a head; they must feel themselves members of some definite corporation, in the administration of whose affairs they ought also to have a voice; and if this be neither the College of Physicians nor the College of Surgeons, as there seems no disposition to take up with the trading Company of Apothecaries, it may be that there shall be nothing for it better than the plan devised by the Marylebone Medical Association. We would fain hope, however, yet to see differences composed, and the profession preserved in its two or three natural integral parts — MEDICINE, SURGERY (embracing Midwifery), and PHARMACY.

MOVEMENT IN THE PROFESSION.

A MEETING of the medical practitioners resident within the borough of Dover was held in the Old Town Hall, on Thursday, Oct. 3d. to take into consideration the Bill introduced by Sir James Graham, "for the better regulation of medical practice." Dr. Stolterfoth in the chair.

After a single leading resolution, a petition was drawn up and adopted, in which the meeting declare, that whilst fully sensible of the anomalous condition of the medical profession, and heartily concurring in the expediency of its revision by the legislature, they still "deprecate in the strongest terms that principle of the Bill which, by removing the stigma of illegality from quackery, throws open the practice of medicine to every unqualified person, as a measure disastrous to the public welfare, and more particularly to the poor, who are utterly incapable of discriminating between the ignorant pretender and the regularly qualified practitioner.

"They farther believe some peal check upon the practice of the unqualified, of easy application, essential to the efficiency of any legislative enactment.

"Though they approve of the establishment of a supreme Council of Health, they cannot but view the constitution of the Council as highly objectionable, none of its members being sufficiently interested in protecting the interests of the general practitioner or licentiate of medicine.

"The proposed system of registration, to be really useful, they think ought to be imperative."

They are still further of opinion, "that any measure of medical reform which does not include the chemist and druggist, who has gradually been occupying the position of the *apothecary*, will be imperfect and inefficient; and that as pure medicines are absolutely necessary to the practice of physic, and much suffering and loss of life annually occur from the present uncontrolled sale of drugs, it is highly expedient to compel all vendors of them to give proof of their knowledge of the qualities and uses of the articles they deal in."

We think the suggestion here made in regard to the chemist and druggist a highly important one, and well deserving careful consideration.

At a meeting of physicians practising in York, and the West Riding of York-

shire, held at Normanton, on Thursday the 17th of October ult., for the purpose of adopting a petition to Parliament on the subject of Sir J. Graham's Medical Reform Bill, Dr. Belcombe, of York, the President of the Association, in the chair, it was determined that a petition be presented to each House of Parliament, in which the meeting declare—

"That they received with the liveliest satisfaction the announcement, that a Bill for the better regulation of medical practice throughout the United Kingdom had been introduced into Parliament, under the auspices of Her Majesty's Government.

"That they highly approve of those parts of the Bill which recognize the preservation of the existing medical institutions, and different classes of medical practitioners, and, at the same time, provide uniformity of qualifications, and equality of privileges, amongst all practitioners of the same class in the three kingdoms.

"That they also fully admit the necessity of some central and controlling body, such as the proposed 'Council of Health,' for the responsible government and harmonious operation of the several medical establishments.

"Believing that the Universities of the United Kingdom are fully competent to ascertain the amount of scientific knowledge, and professional acquirements, of those who are candidates for medical degrees, they pray that that clause of the proposed Bill should be withdrawn, which renders it imperative on all persons who have graduated in medicine in one of the Universities of the United Kingdom, to undergo examination before a College of Physicians, such requirement unnecessarily complicating the tests of professional competence, diminishing the real value and respectability of the honours conferred by the Universities, and involving undue concession to the several Colleges of Physicians.

"They further pray, that physicians should be required to have applied themselves to medical studies during at least seven years, and have attained the age of 27.

"They approve of all legislative discountenance of illegal practice, and humbly suggest that an inquiry be made into the operation of the laws now in existence against such practice in foreign countries, and in the United Kingdom.

"Finally, they pray that such other desirable modifications in the details of the proposed measure may be introduced, as may tend to realise the reasonable wishes of the practitioners of the United Kingdom, to make it efficient, and to secure from ultimate defeat, a legislative effort, made, as they

believe, with the honest desire of obviating the injurious anomalies of a profession, in whose honour and ability are deeply involved the interests of every subject of these realms."

A meeting of the legally qualified medical practitioners of the borough of Gravesend and its neighbourhood, was held at the Literary Institution, Harmer Street, on the 18th ult.; Dr. Hawkins in the chair.

Resolutions were passed, concurring in those parts of the proposed Medical Bill "which secure a better education, and recognise a higher and more uniform standard of qualification, for the members of the medical profession;" but Mr. Humpage, on submitting the second resolution, regretted that Sir James Graham had ever interfered in the subject of medical legislation at all, and characterised the proposed Bill as "mischievous in its nature." The resolution was to the effect:—

"That the meeting regarded with great disappointment and alarm certain clauses which repeal so much of the Apothecaries' Act as relates to the penalties for practising as an apothecary, without supplying any protection in its stead, and which would thereby virtually throw open the practice of medicine to ignorant and unqualified persons, and deprive the public of all security, and the profession of that protection, to which they conceive themselves, from their numbers, respectability, and education, entitled."

We regret that our space does not allow us to give the observations of more than one of the speakers at length, which were characterised by good sense and discrimination. A committee was appointed to draw up a petition in accordance with the views of the assembly, which then separated.

A very numerous meeting of the medical profession, at the instance of the Council of the North of England Association, was held at Newcastle on the 23d ult.; Dr. Headlam in the chair.

The Chairman, in introducing the business, took occasion to speak of the formation of the Association, five years ago, in support of the rights and privileges of the profession. Its labours, combined with those of other associations, had not been in vain. The public were now well informed upon the question, and saw that medical men had no selfish motives in their agitation, but aspired only to raise the character and usefulness of the profession. The Government of the

country had also been roused to action. A Bill had been introduced to the consideration of the Legislature and of the country. For the first time the Government had acknowledged the medical profession as a useful institution, and its title to promotion and protection. The Bill was defective, but he saw in it a basis of sound medical legislation. Fundamental principles had been laid down, on which some measure of reform must ultimately be carried out. The introduction of the Bill would necessarily lead to extended discussion, and the public would see, more and more, that it was of greater importance to them than to the profession that medical reform should be successful. The foundation of that reform should be, in his opinion, the legislative provision of a properly educated body of medical men, and the due protection of them in the exercise of their profession.

Dr. Charlton, the Secretary of the Association, then read a Report from the Council.

Dr. Brown, of Sunderland, moved the first resolution, thankfully acknowledging the obligation conferred upon the profession and the public by the Government, and expressed his conviction, founded on the candid spirit in which the Bill had been received in the provinces, and on his knowledge of the profession in his own district, that the resolution would receive the unanimous concurrence of the meeting. The Government might not have embodied in the Bill all that was required, and they might have introduced some provisions which it would be well to reject; but, in his opinion, they had behaved fairly, and even handsomely, to the medical profession and the country. The proposed measure, he was glad to find, would make the profession virtually a Government department. It proposed to establish a Council of Health and Medical Education. The Government, in his opinion, had too large a share in the construction of the Council. The connection of the profession with the state would be too subservient: it would utterly deprive them, as a body, of self-action; and the general practitioner, having no indirect control, even over the election of the Council, had especial cause to be dissatisfied with the proposal. The other grand defect in the Bill was the complete impunity which it gave to unqualified practitioners.

Sir John Fife, in moving the second resolution (approving of many of the provisions of the Bill, but declaring that, as a whole, it would be more injurious than beneficial), commended the proposal to require a heightened and uniform qualification to practise, but was of opinion that the measure would place the profession in a worse situation than the present. Its fundamental defects were the total absence of all representation of the great body of general prac-

tioners, the most laborious and useful class in the profession, and the omission to impose any direct, or positive, or severe restraint on empiricism. It did seem most extraordinary, that in a country where no man could sell spirits without a license, and where a spirit-vendor must give guarantees of his respectability, any man, the most illiterate and unprincipled, was to have full liberty to take charge of the health, ease, and lives of the people! He hoped the Government would consent to the amendment of their Bill, and thereby entitle themselves to the gratitude of their country.

Mr. Greenhow, of Newcastle, the mover of the third resolution, thought there could be no question as to the desirableness of a presiding body. But he could see no reason why, in the proposed Council of Health and Medical Education, exceptions should be made from the spirit of our free constitution and form of government, derogatory to the honour of the medical profession. It was a poor compliment to say, that they had not sufficient intelligence or honesty to choose their representatives and rulers. It was intended to form them into a great corporation or guild; but the privilege usually enjoyed by incorporations in this country, of electing their governing bodies, was denied to the members of the medical profession, their just claims having been totally overlooked by the framers of the bill. Not only was there no representation accorded to the general practitioners of the empire, but the physicians and surgeons would also be virtually unrepresented, the election of the six physicians and surgeons being confided to the colleges of the three kingdoms, who would doubtless make choice of members or connections of their own self-elect councils. He was inclined to think, from the conduct of the government, that they would feel disposed to listen to the petitions of the profession, and concede their claims to be fairly and fully represented.

We have also intelligence of the formation of a standing committee out of the Liverpool meeting, and that very courteous and satisfactory answers had been received from Sir James Graham, the four Members of the County, and the two Members for the Borough.

RESOLUTIONS

Relative to the Bill for the better Regulation of Medical Practice, adopted by the Royal College of Physicians of Edinburgh, at an Extraordinary Meeting, held on 11th October, 1843.

1st, THAT the College testify their satisfaction that the Bill for the better regulation of Medical Education and Practice, so long expected, has at length been laid before the

House of Commons, and has had a first reading.

2d, That this satisfaction has been increased by the knowledge, that the two great principles of the measure, viz. a uniform standard of education and qualification, and the abolition of all local privileges, are those, for the recognition of which, the College have on various occasions contended.

3d, That the principles now specified, if carried fully into effect, would confer a great benefit on the Profession and the Public, and would remove the evils and remedy the abuses now existing, and of which, for a long time past, there has been too good reason to complain.

4th, That in thus providing the Public with a supply of fully qualified General Practitioners, the College are of opinion that Government is undertaking all that can be properly attempted by legislative interference.

5th, That the College have, with regret, observed that the part of the Bill which proposes to abolish the practice of prosecuting unlicensed and unqualified practitioners, has given rise to great alarm and a good deal of opposition. The College are inclined to doubt the practicability of restraining unlicensed practice by penal enactments, or the expediency of attempting to do so by such means, and in this view they are strengthened by the fact, that such powers, although vested in some of the public bodies in Scotland, have for many years been allowed to lie dormant without any practical inconvenience. But notwithstanding that these are the sentiments of the College, yet, if it shall appear that it is the desire of a large proportion of the intelligent members of the Profession to attempt to restrain such Practitioners by penal enactments,—rather than endanger the final success of a measure otherwise so beneficial, the College are disposed not to urge strongly their own opinions on this head.

6th, That while the College approve most cordially of the general spirit and principles of the Bill, they allow that in various details it may be desirable to introduce certain changes and modifications not affecting its principles or leading details, and which, so far from impairing the efficacy of the measure, would tend materially to facilitate its practical application.

7th, That the best thanks of the College be conveyed to Sir James Graham for the trouble and attention which he has bestowed in the preparation of this Bill, accompanied by a copy of the foregoing Resolutions, and an expression of the hope entertained by the College, that the measure may be, at an early period of the ensuing Session of Parliament, brought under the consideration of the Legislature, and finally passed into a law.

R. RENTON, *President.*

Report by the Royal College of Surgeons of Edinburgh on "A Bill for the better Regulation of Medical Practice throughout the United Kingdom." (Approved of, 4th October, 1844.)

THE Royal College of Surgeons of Edinburgh have observed with the greatest satisfaction that the grievous impediments to the practice of the healing art, arising from the faulty state of the laws affecting the medical profession, of which the College have so long unavailingly complained, have engaged the attention of Her Majesty's advisers; and that a legislative remedy, proposed by them, has been read a first time in Parliament, and has been printed for the information of all who take an interest in the subject of it.

It is satisfactory to the College to discover that the proposed bill is based on the great general principles which they have so repeatedly urged upon the legislature as being of paramount importance and necessity—viz. uniformity and sufficiency in the amount of education required of candidates for medical qualifications; uniformity and sufficiency in the strictness of the examinations to which such candidates are subjected; and uniformity in the privileges to which successful candidates are introduced, in whatever division of the United Kingdom their education and their qualifications may happen to have been acquired.

It is also a leading and a most important principle of the bill to give to the persons thus qualified the advantage of exclusive eligibility to medical offices in hospitals and other public institutions, and to give to the public the advantage of knowing what practitioners are qualified, by the registration and publication of their names at stated periods.

It is the opinion of this Royal College that no measure of medical reform ought to be satisfactory, either to the profession or to the public, which does not embrace all these general principles, and which does not utterly abrogate those partial and exclusive rights of medical incorporations, which, in certain parts of the United Kingdom, have operated so injuriously as impediments to the selection by the public of well-educated medical men for the performance of professional duties for which they would otherwise have been preferred.

The College regret to find that the proposed bill has been objected to by many respectable medical men, on account of its not containing provisions for restraining unqualified persons, by penalties, from practising the profession. The College consider this matter to be subordinate in importance to the great leading features of the bill already alluded to, that neither of the two opposite views of it ought to be urged in such a way as to en-

danger the measure. On the point itself the College have seen no cause to alter an opinion which they expressed *unanimously*, in a report which they published four years ago; an opinion upon which they have uniformly acted for a very long term of years, "that prosecutions will be found to fail in accomplishing the object proposed," that "they may render the unqualified more cautious in practising on public credulity, without making them less successful;" that they may even impart to their pretensions a degree of fame and of importance, which those pretensions would never acquire without such assistance, and "that they may have an unfavourable impression on the character of the qualified, who will be more likely to stand well with the unprofessional part of the public if they have the magnanimity to despise this species of artificial protection, and to rest their claims to public confidence solely upon their professional talents and qualifications." In this view the College find themselves fortified by the concurrence of Sir James Graham, of Mr. Warburton, and of most of those members of parliament who have given attention to the subject. The College trust that the arguments on both sides will be dispassionately considered by the committee on the bill, by whose decision, whatever it may be, they are perfectly willing to abide.

The College further resolved—

1st. That the Medical Reform Committee be authorized to give every possible assistance, by petition or otherwise, to the passing of the bill of Sir James Graham, with such alterations as may seem expedient, provided always that the great principles on which it is based are in no degree impaired by such alterations.

A SKETCH OF THE PRINCIPLES OF A BILL FOR THE BETTER REGULATION OF THE MEDICAL PROFESSION.

BY JOHN DALRYMPLE, F.R.C.S.

THE following sketch I place before the notice of my professional brethren with great and unfeigned diligence. Whether it contains any thing of novelty, or whether it repeats the suggestions of many far abler writers and thinkers upon this subject, I know not; for I have, of design, avoided the perusal of the plans of others, conceiving that some advantage might arise from the promulgation of the independent views of individuals, however humble their place in the profession. Neither

has this sketch been altogether suggested by the bill of the Home Secretary, as lately made known to the public, nor by the various able comments that have appeared upon that bill. Some of the positions, now assumed, were published by me, anonymously, two years since, in the pages of the *Lancet*; but the time is ripe, and the profession apt to the inquiry, whether that bill should be wholly rejected, whether it is susceptible of amendment, or what measures it may be prudent to adopt in its room. The principle of "free trade" in medicine may to some appear fair enough, but the right interpretation of that *cry* is freedom and equal privileges to *those qualified* to practise medicine, and not the unchaining a host of ignorant and designing men, ready at a word to commence their frauds upon the public health, and the private pocket. There can be little question but that the table of the House of Commons will groan beneath the weight of petitions *against* the projected bill, but the question will naturally be asked by its framer, whether the profession as a body have any settled and determined plan to substitute for it. It is with a hope that the medical mind is hastening to this enquiry, that I have been induced to throw together the following observations, enunciating principles of reciprocal protection, which to me, as an individual, appear just and necessary to the future safety of the profession; and with a view not to overthrow, but to conserve and consolidate our existing colleges and boards of national education.

It is necessary to add that these observations have a particular operation only as regards England and Wales, though the extension of the principles to Ireland and Scotland would be obvious and easy enough.

JOHN DALRYMPLE.

56, Grosvenor Street,
Oct. 1844.

I. *Objects of Legislation.*

The protection of the health of the community ought, in justice, to be as much the care of the laws, as that of property, or of the public peace. That this is virtually admitted may be seen in the various sanitary provisions relating to quarantine, drainage of lands, sewerage in large cities, &c. and directly by a recent enactment upon the subject of

vaccination. The government of the country has not only the right, but it is imperative upon it, to prevent as far as possible the public health being endangered by the practice of the ignorant, and the only obvious mode by which this protection can be exercised is, by issuing licenses to practise, and enforcing a previous examination of candidates for the license, as a test of their ability to treat disease.

The basis, however, of all legislation upon the subject of the better regulation of the medical profession should be **MUTUAL PROTECTION**. The demand of an examination test from the person desirous to practise medicine, presupposes a long and painful course of study, notoriously not without its danger to health, and involving considerable pecuniary sacrifices. The medical man who has expended his youth, and impoverished his means, in conforming to the just requirements of the legislature, has the most indisputable ground for claiming immunity from the attacks of unlicensed and unlearned practitioners.

It is equally to the advantage of the non-professional public to be thus compelled to employ only licensed persons, when requiring medical aid, as it is to the government of the country to insist upon certain educational qualifications before it admits the candidate to the enjoyment of public medical appointments. It is already penal for old women to deal in palmistry, or to trick ignorant servant-girls by the arts of conjuration; but the proposed laws contemplate the entire impunity of the more dangerous charlatan, who, outstepping the highwayman, robs at once the unfortunate of his money *and* his life.

The bill lately presented to the House of Commons, by the Home Secretary, in repealing previous statutes, and actually extinguishing the powers of the Worshipful Company of Apothecaries, seeks to remove all those protections from the medical practitioner that at present exist; and by expressly refusing all interference with unlicensed and ignorant pretenders, leaves him in a worse position than before. It is true the proposed bill requires a diploma, or license, from the projected Board of Health, previous to the election of persons to the ill-paid offices held by medical men, but these public

situations are never sought after by the empiric, and are far beneath the aim of his mercenary ambition.

Nor is there any increased security in the fact, that the unlicensed practitioner will be unable to compel payment for his so-called services in a court of justice, for it is well known that, until within the last few years, the general practitioner, duly qualified by law, did not believe he could succeed in enforcing his legitimate demands, and that the physician cannot, at the present moment, legally compel his fee. It is obvious, therefore, that the fear of non-payment for their time and skill never has, nor will in future, deter persons from engaging in the practice of medicine or surgery; and that neither the profession nor the public are protected by this mockery of a bill, from the inroads of the unlicensed medicine-vender, quack-salver, or cheat.

What, then, are the means by which the medical and non-medical public may be *mutually* guaranteed against this danger? In answer to this question, the following observations are submitted in all humility to the judgment of the medical profession.

I. Let every present possessor of a diploma to practise from any of our existing, legally constituted, educational boards, be registered in the order of his standing, and receive a license to practise, and let every future candidate for practice be submitted to due examination before he receives his license, or is entered upon the registry.

II. Let every person entered upon the roll of licensed practitioners pay a small annual *stamp duty* to the government, say £3 or £5.

III. A sum of from 60 to 100,000£ would probably be thus raised to the government, in consideration of which, let the government provide the means for, or sanction the prosecution of, every case of unlicensed practice that shall, upon sufficient proof, be brought before the proper tribunal.

If the facts of medical attendance, coupled with the sale of drugs, or advice given for pecuniary or other emolument, can be proved against the accused, it shall be considered sufficient for conviction to show that the offender's name is not upon the registry, or no defence shall be considered sufficient without proof of his being in possession of a license to practise, and

that he continues to pay his annual duty to government.

IV. For every case of unlicensed practice proved, a fine of £5 shall be inflicted, and after a certain number of convictions a limited term of imprisonment shall undeviatingly follow*.

V. Secret medicines ought also to be dealt with, and it might be provided that such as are already recognised and permitted, should continue the property of the possessor only during his life, and upon the formula or receipt being duly registered at the stamp or patent office. The proprietor of a secret medicine has no juster claim for an extended protection of his nostrum, than the inventor of a new machine, and the law of patents does not permit an hereditary or unlimited property in the discovery.

Board of Health.

VI. To carry out these provisions a "Board of Health" should be established, which, in place of being chiefly the nominees of the crown, as at present proposed, should in fact *represent* the profession at large. It should be their duty to confer the licenses to practise, and to maintain the correctness of the roll or registry of the licensed practitioners.

The Board of Health might also be empowered to strike off the registry such persons as should notoriously offend against the decencies or the science of the profession. Such persons, whose names are still to be found in the annual lists of our colleges, are at this moment regular advertising quacks, venders of secret medicines, and are pulled into notice by the usual arts of advertisement in the newspapers, of bills distributed, and placards posted in the public streets. Persons, also, who have been convicted by a jury of manslaughter or malapraxia (a horrible instance of which has recently shocked the public mind) should be disqualified from future practice, and be struck off the roll accordingly. A precedent for this power is to be found in the profession of the law.

By the constitution of the Board of Health to direct the affairs of the me-

* The present mode of prosecution of unlicensed practitioners is far too costly and too slow to attain the desired end. Such offences should be summarily dealt with before the police magistrate, or before two justices of the peace, in petty sessions assembled.

dical profession, and to confer the licenses to practise, it would appear at first sight that all the powers vested in the existing medical corporations would necessarily cease; that their sources of income would be dried up; and the collections of scientific objects, the work of many years of public and private munificence, be overthrown and scattered to the winds. Such a disastrous event is neither the object, nor would it be the effect of the plan here proposed.

I hold *all our medical corporations* to be useful as they are, and capable by a modified management of becoming the fountains of honour in our general art. I would wish to see them respected for their utility, honoured for their science, and venerated for the high position they might attain, and for the rewards of merit they might be capable of distributing to the most worthy of such distinctions. I would desire to retain unimpaired the Royal Colleges of Physicians and Surgeons, as branches of our national boards of medical education; and I heartily desire to see the Worshipful Company of Apothecaries elevated into a Royal College of Pharmacy, separated from the mercantile department of the present company.

Uniformity of legal rights.

VII. It would be very desirable, and, indeed, the effect of the plan here respectfully proposed, that every person practising medicine or surgery, or both, should receive the same qualification to practise, and that the examination test should be equal for all.

The division of our common profession into subordinate or separate parts is by no means incompatible with an uniform standard of qualification. Although taste, position, opportunities, and the like, may afterwards determine the channel into which an individual may choose to direct his energies, yet it ought to be compulsory, at the outset of life, that he should prove his qualification in any, and all, departments of the healing art.

In this manner an uniformity of the profession would be attained, giving equal rights, conferring equal privileges. The acquisition of honour, wealth, public estimation, would be within the aim of all. No sensibilities would be wounded by unmerited exclusion; no domination of irresponsible corporations

would crush the more modest aspirations of genius. The field being fair and open, extended mental culture and moral worth, crowned with deserved success, would no longer be bolstered up by artificial rank and exclusive privileges.

Distinctive departments of practice.

VIII. Though uniformity of rights be thus secured to the medical profession, yet would I not exclude the possibility of attaining higher honours. While each practitioner would be empowered to select any particular branch of practice, or to combine the whole, he should not be prevented from obtaining distinct honours, which a generous rivalry would accord to those establishing a claim to such distinctions. The possession of superior knowledge, the high cultivation of science (which latter is seldom in our profession accompanied by corresponding pecuniary advantages) should entitle a person to demand, on proof of such acquirements, admission into our present colleges, and to possess himself of their diploma. Some modification, a remodelling, rather than a destruction, of these institutions might become necessary; and I shall have occasion hereafter to advert to this topic, in illustration of the plan I, with submission, present to the notice of the profession.

IX. The title of *medical practitioner* should be understood to signify one licensed to practise medicine and surgery generally; for the art of the obstetrician, oculist, aurist, dentist, &c. are only subdivisions of one general whole, and cannot be safely or advantageously practised, without a knowledge of the laws regulating healthy and morbid function. To obtain such a license as the one contemplated, would demand a higher standard of education than now exists: while the examinations should be *practical* as well as theoretical, a point in which they are at present so profoundly deficient, that the *well-ground* has often great advantage over the *well-grounded* candidate for the professional degree.

Mode of examination of candidates for practice.

X. I would respectfully propose that *all* students, candidates for a license to practise, should pass an examination before *each* of the existing boards of

medical education : but in order to simplify this great object the present Royal Colleges, and the Worshipful Company of Apothecaries, should be restricted to certain departments of science as subjects of examination, the details of which might be hereafter matter of arrangement.

The candidate for a license, prior to being placed on the registry, should be required to produce to the Board of Health certificates, or letters testimonial, of having passed satisfactorily in chemistry, *materia medica*, pharmacy, and medical botany, (midwifery?) before the Court of Examiners of the Worshipful Company of Apothecaries.

2dly. Testimonials of qualification in anatomy, general and special, physiology and surgery, (midwifery?) from the Royal College of Surgeons; and,

3dly. Certificates of examination from the Royal College of Physicians, in pathology, morbid anatomy, therapeutics, and forensic medicine.

The production of these three certificates should entitle the student to a license to practise, and to his being placed on the registry at a proper age, (say not under twenty-three years) and upon payment of a stipulated fee. Each certificate from the examining boards should also bear a fixed fee, which should form a part of the income of each college, and the control and expenditure of these monies should be vested in the council of the respective colleges or corporations.

Fees for examination for license.

XI. It might be provided, also, that though the license to practise would be paid for through separate channels, the total cost need not exceed the present price of obtaining the diplomas of the College and Hall conjointly; for though some of the fees now paid might be lowered thereby, the three establishments would receive an ample equivalent in having a share in the examination of *every medical practitioner*.

The payment of a small annual stamp duty to government, would be compensated to the practitioner in enlarged privileges, and in the conviction that he acquired certain protection in his functions, by the extinction of unlicensed interference. The expenses of the Board of Health, and of maintaining the registry would also be defrayed out of this annual fund.

Diplomas of the Colleges.

XII. It might be further permitted to the existing Colleges to grant diplomas to such persons as, having already a license to practise, desire to exercise a particular branch only, or who aim at the higher distinctions due to a higher standard of education. Thus we might still have our "doctors of medicine" and "masters of surgery," of whom should consist the body of *Fellows* of each College; but of this rank ought the council to be chosen, and the *Fellows* generally ought to be the electors.

It would be possible for the Worshipful Company of Apothecaries, if raised into a Royal College, to which their meritorious exertions of late years in elevating the standard of qualification fully entitle them, to constitute a higher honorary distinction than at present exists; but however that might be, the self government of the Colleges and Hall should remain with the *Fellows* and Members thereof.

Honorary Distinctions.

Suppose a person, already possessed of a license to practise from the Board of Health, gifted with an ardent mind, his opportunities, may be, directing him to the practice of a particular department of his profession, claim those higher distinctions to which extended science would fairly entitle him. He devotes himself to medicine, and offering himself to a further ordeal and test of merit at the Royal College of Physicians, he aspires to the Doctorate; or, desirous to take a lead in surgery, he applied for the honorary diploma of the Royal College of Surgeons—would any be envious of his success? It is his devotion to the acquisition of knowledge, and the proof of his having deserved this reward, that would disarm the cavillers. He acquires no further right, no exclusive privilege; it is this honour alone to which he aspires, and a College composed of such "*Fellows*" would indeed rank high with the general body of the profession, and need fear no rival, no detractors.

Education of Students.

XIII. As, however, it must be granted that the mass of information required for the safe granting of a license to practise is very considerable, as well as of various kinds, it would be prudent and more convenient that all the examinations should not be delayed until

the period of obtaining the license. The time to be occupied in medical studies should be fixed at a minimum period, and at the expiring of certain minimum terms (and not before) the student should be entitled to demand his examination in separate and particular branches of medical science, and on satisfaction of the examiners a certificate to that effect be granted.

The candidate should have the option of choosing the order in which he would present himself at these separate examinations, as the period of his proficiency in certain departments of knowledge might depend in individual cases upon opportunities it would be fair to give him the advantage of*.

XIV. It might, however, be very desirable that even a preliminary examination in the *literæ humaniores* be instituted, without a certificate of competence in which, the student should not be permitted to commence his medical studies.

It must be conceded by every reasonable person, that means of acquiring a knowledge of any science or profession ought to be altogether unfettered, untrammelled by any conventional restrictions; in short, that facilities should be offered at least, and the enjoyment of those facilities rendered as little costly as is compatible with the fair remuneration of the teacher. The present system of a prescribed curriculum, a compulsory attendance of students at certain places, and in defined seasons, is by no means necessary to the acquisition of the required knowledge, and a cursory glance will expose one of the difficulties that now besets the student in obtaining a full and practical acquaintance with the preliminary branches of science.

A thorough knowledge of anatomy cannot be derived from lectures and books merely—only, indeed, by a close

attendance in the dissecting room. The time, however, that ought to be devoted to one of the most essential studies is broken up, and frittered away by a compulsory attendance upon daily and almost hourly classes. The mind of the student is distracted by the too various subjects of inquiry, and his health is impaired by the miasma of the bodies, which decompose upon the table from his want of time to complete sufficiently early the commenced dissection.

Evils of this nature, it is true, have been recognised, and partially, though imperfectly, guarded against, by spreading the whole system of education over a greater space of time; but why, may I ask, might not the student be permitted to make himself master of medical botany, a knowledge of chemistry, materia medica, and pharmacy, or any of the collateral branches of his art, at any period of his apprenticeship, if apprenticeships, as they now exist, are to be continued at all? The examinations he is required to submit himself to, ought to be sufficient test of his proficiency in the sciences, and he ought to be left free to obtain such knowledge in any manner that his means or opportunities place within his power or convenience.

There is, however, one restriction it might be advisable to make, and that is, the student should be compelled to devote a certain definite period to attendance in the wards of a sufficiently large hospital or infirmary of the United Kingdom. However valuable may be the science taught in foreign hospitals; however large may be the experience of their medical officers, and unbounded as are the facilities offered by the continental establishment for the sick, still he ought to be required to attend a certain definite time at our own home hospitals, that he may inform himself of the practice experience has shown to be best suited to disease, modified, as it is, by the peculiarities of our climate, by hereditary dispositions, or the characteristic differences of our British mode of living. With this exception, I would leave the mode or order in which the student acquires his professional information as free and unfettered as becomes the spirit of a liberal and scientific profession.

Licensed Assistants.

XV. Having thus presumed that the

* The order which a student would pursue in acquiring the various branches of science and art necessary to the perfection of his education, would, without being compulsory, soon take a natural course. He would, for the purpose of facilitating his future labours, commence with chemistry, materia medica, &c. and pass the examination of the Company of Apothecaries, prior to the study of pathology and therapeutics, and as these would almost necessarily be the last topics of inquiry, he would previously make himself master of anatomy and the laws of healthy function. Hence, his second certificate of examination would be that of the Royal College of Surgeons. This, I repeat, would be the natural order, and generally followed, without the absurdity of a compulsory curriculum.

candidate has satisfactorily passed his preliminary examinations, and obtained the certificates then granted to him, he should be qualified to require of the Board of Health his general license to practise. But, should circumstances arise which induce the student to delay this proceeding, I would give him the power, by registering his certificates, (gratuitously) to take the place of a licensed dispensing or visiting assistant to a duly qualified practitioner.

XVI. *The administration of the affairs of the medical profession* comprises the formation of a *registry*; the conduct of elections; the granting licenses to practise; the control of the finance department; and the medium of communication between the Government of the country and the medical profession. Hence, these matters must be committed to the direction of a central board or council, to be elected out of the *general body of the members of the profession*.

Council of Health.

It is not a concession to the feelings of the profession, but a right inherent in it, that the election of such a council should be popular and unlimited; in other words, that each person who has qualified himself to practise ought to be qualified to vote for the appointment of councillors, and himself be eligible to become a candidate for the office. The only restriction it would be prudent to make would be the attainment of a certain age (say 30 years), and, as of necessity, the sittings of such a central board must be in London (for England and Wales), the members thereof should be required to reside in, or within a certain distance of, the metropolis.

XVII. Suppose, however, that the council be limited to thirty six, (whereof nine would be *ex-officio members**), and of these nine should vacate their seats annually, it would follow that an annual election of nine councillors must take place, by means of an enormous constituency, and one spread over the whole surface of England and Wales.

Supposing, also, that the form of election were by printed lists forwarded to each elector, the registrar requiring

him to return it signed, and with the names of the candidates chosen by him, clearly designated; still the vast bulk of the constituency would give rise to serious difficulties, and the qualification of candidates would in the great majority of instances be wholly unknown to the electors. Hence the choice might often fall upon the least eligible candidate, and chance too much operate where prudence and judgment ought alone to prevail.

Is it not possible, however, so to construct the machinery of elections, as to obviate many of the difficulties, without dispossessing them of that character of freedom and popularity which ought to be the basis of all representation? I think it is: and to this point I would invite serious attention.

Registration.

XVIII.—All persons already licensed to practise, and all persons who may in future receive a diploma or license to practise, should be registered in the order of the respective dates of their diplomas, and should receive a properly signed and sealed certificate thereof.

It should also be required that an annual registration be made of all persons qualified to practise, with their respective christian and surnames, places of abode, and if required, their honorary titles and distinctions; that lists should be printed under the authority of the Board of Health, and given to each practitioner on demand. That this registration should have legal force, and upon a person proving himself to be the individual named in the authorised printed list, he should require no further evidence of his qualification to practice.

Registration in Districts.

XIX.—The machinery for such annual registration should be as follows. A registrar should be appointed for each metropolitan borough, and for each county of England and Wales, his salary to be proportioned to the size of and the number of practitioners within, his district. He should keep a book, wherein by a certain fixed day in each year he should see that each licensed practitioner in his district signed his name and place of abode. At the first registration of any practitioner he should be required to show his diploma, but, having once been registered, the production of the diploma should not

* The President and two Vice-presidents for the time being of the Royal Colleges, and the Master and two of the Court of Assistants of the Worshipful Society of Apothecaries.

be required while he continued to live in the same district.

Within a month after the completion of the district-registry—the registrar should transmit it to the Board of Health, or Central Council, and by them a complete list of members licensed to practise in England and Wales should be made out and printed—and that too by a definite period in each year. The registry of the preceding year to have legal force until the next list be published. Such a registration, it will be seen, is necessary as a preliminary to all elections.

District Committees.

XX.—The licensed practitioner thus registered in districts, should elect triennially three or five persons, to act as district councils (when in the counties to be resident in the metropolitan town of such county), and who should act as the representatives or *proxies* of the medical practitioners, in the election of the Board of Health; and it will hereafter be shown that other and important duties might devolve upon these district committees, thus :—

1st. Each licensed practitioner would be represented primarily by his proxies in the district committees, and this election would be wholly popular.

2d. It is more than probable, that the persons elected as proxies or district committee men, would be amongst the most eminent and respectable practitioners of the county towns; and it is certain that the character and qualifications of the candidates for so honourable an office would be generally well known to their brethren of the respective districts.

3d. The persons elected, being, it is presumed, the most eminent and upright men resident in the provinces, would feel they held a responsible position in the right of voting for the Central Council, and would undoubtedly be in a better position from their standing and more extended acquaintance, for examining into and judging of the qualifications of candidates for the Metropolitan Council or Board of Health.

4th. The number of actual voters for the Central Council would be reduced to about 300*, and greatly facilitate,

from their comparatively small numbers, the labour and certainty of this the most important of all the elections.

The mode of conducting this election is by no means difficult.

The borough and county registrars should print a list of candidates for the district committee, and send such a list to each practitioner within his district. The list should be returned on or before a certain day with the proper number of names selected, and the paper signed by the elector. His signature being compared by the registrar, or by scrutineers, with the signed registration book, and found to correspond, the votes should be cast, and the individuals having the greatest number of votes would become the district committees, and the *proxies* to vote for the members of the Board of Health.

Election of Council.

XXI.—The same form might be adopted in the election of the Board of Health, the constituency being in this instance the 295 distinct committee men, acting for the 15000 or more practitioners at large. In such a manner a fair and popular election would be secured, and at the same time an intelligent and cautious selection of candidates effected.

The appointment as district committee man would be sought for as an honourable distinction, while the trust reposed in him by the provincial practitioners would ensure the necessary responsibility, since his re-election might mainly depend upon the manner in which he executed his several functions.

Many advantages, I am inclined to think, would arise out of the appointment of these district councils. It would be a return to some of our Saxon institutions, the local self-management of our guilds and corporations, and would obviate some of the evils of centralisation. Complaints against unlicensed practitioners might be examined by them, and if the charges were borne out by inquiry, they might be laid before the magistrate, and conviction insured. I believe also, that breaches of medical etiquette and the quarrels

for the 52 counties of England and Wales, 260 such proxies—add to these the metropolitan boroughs, for the purpose of facilitating the voting of London practitioners (London, Westminster, Southwark, Finsbury, Lambeth, and the Tower Hamlets,) 35, or a total of 295 proxies.

* If the number of the District Committee men be limited to five, for each county, we shall have

that occasionally will arise amongst medical men, would often be referred to these councils, by the disputants, as to a tribunal or court of honour, and their mediation would often compose such differences, and prevent the injurious scandal of a more public course.

Finally, such a board would not unfrequently be consulted by the local municipal authorities upon questions relating to the general health, in cases of epidemic disease, in investigating the causes of unusual mortality, and the like.

ROYAL COLLEGE OF SURGEONS.

To the Editor of the Medical Gazette.

SIR,

You did me the favour to insert some remarks respecting the omission of my name from the first list of Fellows of the Royal College of Surgeons, in which I referred to my claims being superior to those of many gentlemen who were elected, both as regarded seniority, and also from my being the successful competitor for the Jacksonian Prize Essay, on one of the most important subjects in surgery (lithotomy and lithrotomy), and author of other works. On which account, most of the chief medical societies and academies on the continent had conferred upon me their honorary diplomas. The writer of an anonymous reply to my letter, acknowledged that some of those who had strong claims might have been inadvertently omitted, which omissions the subsequent list was intended to rectify; and recommended those who felt themselves aggrieved to wait for its appearance. Inadvertency, however, could not have been the reason of my exclusion, as I had previously stated my claims, and afterwards sent a note to the College to inquire the grounds upon which they were not allowed; to which I received no other answer than that it had been laid before the Council;—and perceiving that my name has been also left out on the present occasion, I considered that I ought to protest strongly against so manifest an act of injustice, although estimating the very questionable honour of the Fellowship at its true value, and being aware that its being conferred or withheld from me could not affect my position in the estimation of the profession.

Your correspondent observed, that all persons who write books are not to be considered as having promoted the advance of science, in which I cordially concur; but as the allusion referred to me, I am perfectly willing that the utility of my publications should be judged from the expressed opinions

of the medical periodicals in this country, as well as in France and Germany, and from the circumstance of some of them having been thought worth reprinting and translating abroad. At all events, I have done my best endeavours to be useful, as far as my opportunities would allow, at considerable loss and inconvenience to myself; having spared neither time nor expense in investigating points of continental practice, which I thought might be advantageously made known to the profession in England.

I am, sir,

Your obedient servant,

EDWIN LEE.

Upper Southwick Street,
Oct. 16, 1844.

PROTEST.

To the President and Council of the Royal College of Surgeons.

Gentlemen,—Feeling confident, after the sacrifices which I had made in my endeavours to promote the science of medicine and surgery, that an impartial estimation of my claims would have entitled me to be named among the first of those who were elected Fellows of the College under the new charter, I cannot but consider the intentional omission of my name from the list which has just appeared, as an affront attributable either to the exercise of an influence hostile to me individually, or of the unfair partiality which in other instances has afforded such strong grounds of complaint; and I protest against the injustice which has been done me by so unwarrantable an abuse of delegated power.

I am, sir,

Your obedient servant,

EDWIN LEE.

Upper Southwick Street,
Oct. 16, 1844.

LIGATURE OF A POLYPUS OF THE BLADDER.

AUGUSTA S., 45 years of age, unmarried, had long complained of pain and difficulty of making water, of bloody urine, &c.; when one day suddenly a dark red body, which bled freely, presented itself between the labia. Careful examination discovered it to be a polypus, the size of a hen's egg, and projecting from the urethra, which could readily be entered with two fingers, and the pedicle of the polypus, which was one third of an inch thick, followed into the bladder, without however getting to its point of attachment. I succeeded in throwing a ligature round it by means of two elastic catheters, and then with a proper canula, constricted it as far within the bladder as I could reach. On the third day the ligature was tightened, and on the sixth the polypus fell off. The patient recovered completely.—*Dr. Thiénnemann, Medicinische Zeitung, No. 9.*

DISINFECTION OF SEWERS, CESSPOOLS, &c.

M. SIRET finds, after a great variety of trials, that a quantity of a mass composed as follows:—

Sulphate of iron . . .	200 lbs.
Sulphate of zinc . . .	25 „
Vegetable charcoal . .	10 „
Sulphate of lime . . .	265 „

in all 500 lbs., thrown into a sewer or cess-pool, has the power of disinfecting it in a very remarkable and effectual manner.—*Comptes Rendus*, Vol. xix. No. 5.

CREASOTE IN NÆVUS MATERNUS.

DR. THORNTON informs us that of all the applications he has tried against nævus (telangiectasis), the most effectual is creasote. He had treated three cases in the course of the year successfully with this substance. It is applied two or three times daily more or less diluted. Excoriation, ulceration, and gradual disappearance of the nævus ensues; the cicatrix had always been smooth and sound.—*Medicinische Zeitung*, No. 9.

THE LONDON MEDICAL GAZETTE,

BEING A
WEEKLY JOURNAL

OF

Medicine and the Collateral Sciences.

FRIDAY, NOVEMBER 8, 1844.

REPORTS,

By H. FEARNSIDE, M.B.,

OF

CASES TREATED IN UNIVERSITY COLLEGE HOSPITAL.

Cough of twelve months' duration, and failure of the health during the same period. Recent acute attack—pyrexia—little expectoration—after some days sudden increase in its quantity—remarkable fetor of the expectoration—signs of disease in the apex and base of the right lung—development of amphoric respiration, pectoriloquy, gurgling—rapid emaciation—death. Large effusion in the right pleura—gangrene of the right lung—pneumonia of the left one.

GILBERT RAYMOND, æt. 28, admitted into University College Hospital, under Dr. Taylor, June 9th, 1843. A man of ordinary stature, slight conformation, and sallow complexion; he is a shoemaker, which occupation he has always followed; he is a single man; has always had a sufficiency of wholesome food and warm clothing; he is not in the habit of habitually taking either fermented or spirituous liquors. His parents are living and healthy; he has seven brothers and sisters, all of whom are healthy. He is a native of the Puy de Dome, in Central France, where he resided until he was 18 years of age: during this period he has no recollection of having had any illness; his breath, however, has always been rather short, but he was not then, nor has he subsequently, until within the last twelve months, been subject to cough; and he never had hæmoptysis. At the age mentioned he went to Paris, where he remained for nine years. During this period he was (to use his own expression) "very gay," but escaped without any more serious indisposition than a venereal affection. He has been in London about eleven months, and has

resided during the greater part of this time in a rather close and unhealthy situation in the neighbourhood of Golden Square.

Soon after his arrival in this country, an eruption of small pimples appeared upon various parts of his body, and was considered to be of a syphilitic nature by a medical man under whose care he placed himself. He also began to suffer from various symptoms of disorder of the digestive organs, such as a sense of oppression in the epigastric region after taking food. About the same time, also, he began to cough a little, and principally in the morning on first rising, and he became weaker, and less equal to his employment than he had previously been. He sought the relief of these symptoms in empiricism, and attended for some time at the Homœopathic Institution, but without benefit. He then attempted to follow the system of "vomi-purgatives," adopted by some Parisian charlatan, but equally without advantage. About the latter end of April, or beginning of May, being one of a party collected to celebrate the birthday of a friend, he danced much, became very warm, and returned home late at night, and very thinly clothed. He shivered much, both at the time and afterwards; but no other obvious signs of disease appear to have presented themselves in addition to those previously existing. About a fortnight after this date, however, on attempting to carry a load, which he could formerly have borne without difficulty, the exertion fatigued him so much, that he felt its effects for three days afterwards.

About fifteen days ago, as he suffered considerably from dyspnoea, which he attributed to flatulence, he went out for a walk, and, upon returning home, he felt exceedingly weak and languid, had much headache, heat of skin, and thirst, but no increase of cough. At this time he ceased attending to his employment. Three days afterwards he became so ill, that he was obliged to remain in bed. Nine days ago he had rigors; he

began to cough more, and suffer from pain in the upper part of the right side of the chest, about the third costo-sternal articulation; this pain, he states, has since been gradually travelling downwards. From the report of the medical man under whose care the patient was, it appears that at this time there was dullness on percussion over the lower part of the right side, and that a crepitant rhonchus was heard over the same situation, but whether the fine crepitation characteristic of pneumonia or not, is doubtful. Soon after the development of these acute symptoms, the patient began to expectorate a tenacious reddish or brown fluid; a few days ago he began to expectorate suddenly, and in large quantity, a foetid, yellowish-grey, purulent liquid, and this has continued up to the present time. The treatment adopted consisted in the administration of small doses (gr. $\frac{1}{2}$) of tartarized antimony; but the cough has increased much in severity, the breathing has become more difficult, and the patient has rapidly lost flesh and strength.

State upon admission.—His complexion is pale, and rather sallow, and his appearance altogether cachectic. He generally lies upon his back or left side, as resting upon the right side increases the violence of the cough. He is most free from cough when in the erect posture. The surface generally is rather hot. He has no pain about the head, but feels giddy on sitting up; he sleeps indifferently.

He has some feeling of dyspnoea, and the number of respirations is 28 per minute; he has considerable pain over the situation of the costal cartilages upon the right side of the chest; he suffers much from a violent and frequent cough, and expectorates a large quantity (six or eight ounces in twenty-four hours) of a thin yellowish-grey fluid, which contains a good deal of air, and exhales a peculiarly foetid odour.

The left side of the chest appears to move more than the right one in respiration. About an inch below the nipple the right side measures a quarter of an inch more than the left one; the vocal fremitus is greater upon the right than upon the opposite side. Under the right clavicle, and over the upper part of the right side of the chest, the sound on percussion is somewhat dull, and the respiratory murmur over the same space has a bronchial character, especially in expiration. The lateral surface of the right side of the chest is dull upon percussion; and this is observed even when the patient lies upon the opposite side. The sound on percussion under the left clavicle is not very resonant, and the inspiratory murmur in this situation is rough and prolonged. Posteriorly, the greater part of the right side is dull upon percussion, this being

more marked over the upper and lower, than over the middle third. Over the upper half of this side the respiratory murmur is feeble, and accompanied by a submucoous rhonchus; over the lower part of the side it is inaudible. Upon the posterior surface of the left side the respiratory murmur is feeble, but less so than upon the opposite side.

The impulse of the heart is rather strong, its sounds healthy; pulse 96, soft and compressible.

The breath has the same foetid odour as the expectoration; the tongue is coated with a brownish-white clammy fur; he complains of having constantly a disgusting taste in his mouth from the expectoration; he is very thirsty; has no appetite, and suffers much from a sense of oppression about the stomach after taking food. His bowels are rather confined; his urine pale, sp. gr. 1020, and unaffected by heat or nitric acid. He has no pain or tenderness on pressure upon any part of the abdomen; the liver does not descend below the margin of the ribs.

Treatment, and progress of the case.—Tartarized antimony was prescribed in moderate doses (gr. $\frac{1}{2}$), and the patient was placed upon low diet. For some time the only alterations which he presented were, an increase in the amount of debility and emaciation; the cough and expectoration continued as before; there was no pain about the chest, but the patient complained that coughing occasioned pain in the left iliac region. The degree of fever was not considerable, and the physical signs observed from time to time were but a repetition of those remarked on his first admission. His increasing debility indicating the propriety of a change in the mode of treatment, on June 21st the antimony was withdrawn, morphia in small doses ordered to be taken night and morning, and he was placed upon a more nourishing diet. For a few days the change appeared to be beneficial; he slept better, his cough was less violent, the expectoration less profuse, and he repeatedly expressed himself as feeling much better in every respect; but the improvement, however, was delusive, and the further progress of the case will be best exhibited in the daily reports.

June 26th.—The morphia appears to be losing its effect upon him; he does not sleep so well, and coughs more; the expectoration also has increased in quantity, and is equally foetid as when first observed. There is considerable thirst, and heat of skin. The left side of the chest as a whole, moves more in respiration than the right one. On percussion below the right clavicle, the sound elicited is much duller than upon the corresponding part of the opposite side; from the

second intercostal space to the fourth rib, the sound is considerably clearer; from the fourth to the sixth rib it again becomes duller, and below the last mentioned point it is perfectly dull. Over the right infra-clavian space, the respiration is bronchial, and has somewhat of this character from the second to the fourth ribs; in the latter situation, and near the mamilla, respiration is less distinct, and the expiratory murmur is occasionally bronchial, and almost amphoric; a mucous rhonchus is also heard at the same spot. Below the fifth rib the respiratory murmur is inaudible. On the lateral surface of the right side of the chest, the sound on percussion is dull over the upper third, less so over the middle third, and completely so over the lower portion of the side. Upon the fourth rib laterally, respiration has an amphoric character.

Posteriorly there is dullness on percussion on the right supra-spinous fossa; the sound is less dull on the infra-spinous fossa; below the inferior angle of the scapula it again becomes duller, and is perfectly so over the lower part of this region. The vocal fremitus is stronger upon the lower part of the right, than of the left side. Over the right supra-spinous fossa, respiration is less feeble, with somewhat of a bronchial character; over the middle portion of the right back it is strongly bronchial, almost amphoric; over the inferior third it is inaudible. The vocal resonance is strong over the middle third of the right side, and has much of the character of oegophony; over the right infra-spinous fossa, there is also considerable vocal resonance.

The upper part of the left side is less resonant upon percussion than the lower portion.

B. Ferri Iodidi, grs. iij.; *Aquæ*, f3j. *M. fiat haustus, ter die sumendus.*

June 30th.—During a severe paroxysm of coughing this morning, he expectorated about 2 or 3 oz. of blood, and his expectoration has since been tinged with that fluid. He perspires rather freely; pulse 112, and very soft; respirations 28 per minute. (The morphia to be increased from $\frac{1}{4}$ to $\frac{1}{2}$ gr.)

July 1st.—There is perfect amphoric respiration, and pectoriloquy over the lower part of the right side of the chest posteriorly, extending from the seventh to the tenth ribs, near their angles; less distinctly heard near the spine, or upon the lateral surface of the chest, though still very characteristic in the latter situation. There is increased vocal resonance under the right clavicle.

July 3d.—The expectoration is rather less in quantity, more consistent, and it contains some parts which are of a dark purple colour; he coughs less; the skin is hot and dry, especially that of the chest; pulse 132, and small; respirations 32 per minute. During

the last day or two, he has experienced a sharp lancinating pain about an inch below the right nipple on coughing, or turning suddenly. His tongue is covered with a coat of clammy mucus; he is very thirsty; he takes a moderate quantity of food, and with some relish. Below the right mamma, also on the lateral surface of the right side, and about the same level, there is a distinct double friction sound. The amphoric respiration remains as distinct as before, and is more extended. The left side of the chest, both anteriorly and posteriorly, is less resonant than natural.

Omitatur Ferri Iodidum. Applicentur Hirudines vj. lateri dextro.

5th.—He no longer experiences the same pain as before the application of the leeches; the friction-sound continues audible both near the nipple and upon the lateral surface of the chest; in the latter situation, about the level of the fourth rib, some sound of gurgling is heard. The cough is less frequent and severe, and the expectoration is greatly reduced in quantity; the skin is less hot; pulse 112; respirations 28 per minute. The bowels are much confined.

The leeches to be repeated, and a dose of aperient mixture taken.

6th.—He complains that the cough occasions much pain in the lower part of the right side of the chest; the expectoration continues less in quantity, but has a more strongly foetid odour; pulse 122, and small; respirations 30 per minute. The cracked-pot sound is occasionally heard on percussion near the right nipple; the friction-sound is still faintly heard, but the amphoric respiration is less distinct upon the lateral surface of the chest. Posteriorly, the dullness on percussion on the right side of the chest extends from its inferior margin to a little above the inferior angle of the scapula.

Five grains of Carbonate of Ammonia, in combination with *Sp. Æth. Nit.* and Camphor, to be taken three times daily.

7th.—The debility and emaciation appear to be progressing rapidly; his voice has a peculiarly hollow character; the cheeks are collapsed, and he answers questions tardily, and with hesitation. He coughs and expectorates less, but the pungency of the sputor both of the breath and expectoration appears to be increased; pulse 136, small and feeble; respirations 36 per minute. The space over which the amphoric respiration, and pectoriloquy, can be heard, appears to be extending; the respiration is strongly cavernous upon the infero-lateral and posterior parts of the right side of the chest; the friction-sound is no longer heard.

The medicines to be omitted; 2 oz. of wine daily.

8th.—In the after part of yesterday he had a return of the hæmoptysis, coughing up at intervals about half a pint of florid blood; for the relief of this symptom some acetate of lead, and morphia, was prescribed. At present he lies in a half-dreamy state, and appears to comprehend but little of any questions proposed to him. Pulse 130, very small; respirations 36 per minute. The expectoration consists of a brown purulent matter, floating in a thin, frothy, dark-brown, and excessively offensive fluid. The sound of gurgling is heard over the lower part of the lateral and posterior surfaces of the right side of the chest.

9th, 1 P.M.—He is evidently sinking. The face has a leaden hue, and the hands and feet are somewhat livid; he appears conscious, but without power to articulate distinctly; pulse 160, sometimes almost imperceptible; respirations 60 per minute. He was slightly delirious during the after part of the day, and died about half-past 10 P.M.

Examination of the body, 15½ hours after death.

The body was much emaciated; there was no œdema of any part; the muscles on the right side of the chest were rather discoloured.

Head: The cranial bones were thin and soft; the membranes of the brain healthy; there was but little serum under the membranes, and about half a drachm in each lateral ventricle. The vessels on the surface of the brain were rather full; the substance of the brain generally was congested, the red points being numerous, large, and of a deep colour. Weight of the brain 3 lbs. 2 oz.

Larynx: The mucous membrane of the larynx was rather green, but neither injected nor ulcerated; nor was that of the adjacent portion of the trachea.

Chest: The *right pleura* was universally thickened, and especially so over the lower and middle lobes of the lung, and over the lower part of the upper one; there was an effusion of recent lymph upon its surface. The lungs being inflated, it was seen that there was no perforation of the pulmonary pleura. The base of the right lung was adherent to the diaphragm, the connection being not very recent. The pleural sac contained about three pints of highly fœtid, light-yellow serum, turbid from the presence of shreds of lymph. The *right lung* was much diminished in volume, especially in its middle and lower lobes. The substance of the posterior part of the lower lobe, especially superiorly, was soft, of a dark-green colour, and contained a quantity of thin, dark, highly fœtid putrilage; its tissue was heavier than water. The consistence of one part, about the middle of this surface of the

lower lobe, was so much diminished that the tissue was removed by a stream of water; the subjacent pulmonary substance was generally of an ash-grey colour, but at one spot it had a brownish-green hue. The anterior portion of the lower lobe was less soft, dark-coloured, and fœtid; it contained little air, but did not sink in water. The upper lobe was dense, and contained less air than natural; its texture was dark-coloured, and some frothy serum exuded on incising it. The middle lobe was simply rendered denser by compression; it contained some air in its lower part. The anterior and middle portion of the upper lobe was the least dense part of the whole lung; the summit floated in water. Neither tubercle nor abscess was found in any part of the lung. The mucous membrane of the larger bronchi distributed in the lower lobe of the lung was of a uniform red colour, but not altered in consistence or thickness; the mucous membrane in the non-gangrenous portions of the lung was pale. Weight of right lung 1 lb. 1 oz.

The *left pleura* was free from adhesions, nor did its sac contain any fluid. The anterior portion of the *left lung* was rather pale externally; its posterior surface was dark-coloured, especially in the upper part of the lower lobe. On being incised, the lower lobe, especially near its posterior surface, was seen to be of a dark-red colour, and was much denser than natural. The whole lobe contained much frothy bloody serum, but every part of it floated in water. The inferior and posterior portions of the upper lobe presented similar characters. The mucous membrane of the larger bronchi was somewhat red; that of the smaller tubes leading to the inferior part of the lower lobe still more so, being of a deep crimson colour; the lining membrane of the small bronchi in the upper lobe was pale. Weight of left lung 1 lb. 4½ oz.

The *pericardium* was transparent; there was no fat beneath it; there was a small white patch upon the anterior surface of the right ventricle. The walls of the *left ventricle* were rather thin; its capacity small; the endocardium was slightly opaque towards the base of the ventricle; there were a few spots upon the mitral valve; the aortic valves were healthy; the mitral orifice was of natural size. The walls of the *right ventricle* were rather thick; its cavity small; the endocardium and valves were healthy; the orifices of normal size.

The *auricles* were natural in appearance. There was a small fibrinous coagulum, and a little black blood in the right ventricle; no blood in the left ventricle; a little in the left auricle, and much in the right one—principally black and fluid—with some fibrinous coagula. There were a few spots

upon the lining membrane of the aorta. Weight of the heart 7 oz.

Abdomen: There was a slight amount of redness of the lining membrane of the small curvature of the *stomach*. In the great cul-de-sac the mucous membrane was thinner than natural, the veins dark, and the whole softened (by gastric juice). The membrane was everywhere mamillated except in the cul-de-sac.

No signs of disease were apparent upon the external surface of the *intestines*. The mesenteric glands were healthy.

The *spleen* was firm in texture, and of average size. Weight 6 oz.

The upper surface of the *liver* in contact with the diaphragm, and the inferior border in contact with the intestines, were of a dark-green colour; internally its substance was pale. Weight 2 lbs. 14 oz.

The *kidneys* were dark-coloured and congested. Weight of each 4 oz.

REMARKS.—Several difficulties opposed themselves to the formation of a precise diagnosis in this case, especially in the first instance. The account given by the patient of himself was imperfect, often contradictory, and it was only by repeated interrogation that anything like truth could be arrived at; moreover, it was exceedingly difficult to get the patient to speak to *facts*, as he was perpetually obtruding some fancied *explanation* of the symptoms under which he either was or had been suffering. From his statements as to the failure of his health, and the existence of cough during the preceding ten months, from his emaciation and general aspect, and still more from the ascertained existence of some consolidation in the upper part of the right lung; it appeared probable, upon a *prima facie* view, that the case was one of phthisis. But there was also evidence of the recent supervention of some acute disease, and that this was pneumonia was indicated by all which could be made out from the statements of the patient and his medical attendant. Many of the physical signs observed upon his admission tended to corroborate this supposition, viz. the dulness on percussion, and feeble vesicular respiration over the lower part of the right side. Again, the changes which had taken place in the expectoration; its absence, or existence in small quantity only in the first instance, with its subsequent sudden increase, at once suggested the idea of the bursting of an abscess. But nothing has yet been said of the remarkable fœtor of the expectoration; this is a character which may occur in several diseases. In phthisis a portion of lung becoming detached, remaining in some cavity, and, aided by the warmth, moisture, and air of the part, quickly running into decomposition. In empyema, with ulceration

of the pleura, the fluid passing into the lung, and being subsequently discharged by the bronchial tubes. In abscess of the lung the expectoration is often fœtid, and is generally so in pulmonary gangrene. Fœtid expectoration has also been observed in abscess of the liver, opening into the lung—the liver being adherent to the diaphragm, and the diaphragm to the base of the lung. According to Andral and others, in some cases of chronic bronchitis the expectoration is either constantly or occasionally fœtid; and it possesses the same character in many cases of dilated bronchi. The question next presents itself, of which of these diseases was the case in question an example?

Phthisis.—The probability of the existence of some consolidation (probably of a tubercular nature) in the upper part of the right lung has already been noticed; but the supposition that the case was simply one of phthisis, was opposed by the simultaneous existence of consolidation of the lower part of the lung, the sudden accession of acute symptoms, the extent to which the disease had apparently advanced, and the fœtor of the expectoration, which though sometimes observed, is nevertheless rare in phthisis.

Empyema.—This supposition was negatived by the absence of enlargement of the affected side; the patient could lie better upon the left (healthy) side than upon the right one; there was no displacement of the liver, and the vocal fremitus was stronger upon the diseased than upon the opposite side. The dulness on percussion was not altered by change of posture, and the expectoration, though profuse, was less so than it commonly is in empyema.

Hepatic abscess opening into the lung.—This opinion was opposed by the absence of any signs of disease of the liver; there was no enlargement of that organ, no pain or tenderness upon pressure over it, and jaundice had never existed. It must be observed, however, that in some exceptional cases abscess of the liver may take place without any obvious previous signs of disease of that viscus.

Pulmonary abscess and gangrene.—From repeated observation of the physical signs, which are specified in the history of the case, it was obvious that there was disease in the lower part of the right lung: was this abscess or gangrene? The expectoration was at first scanty, then it suddenly became abundant; an occurrence more likely to take place in abscess, than in gangrene of the lung. In six out of twelve cases of abscess of the lung, noticed by M. Grisolle, the expectoration took place suddenly; this, however, is no proof of the existence of abscess, as the sudden expectoration of purulent matter in large quantity, leading to the supposition of the existence of

empyema, may occur from the bronchial tubes alone. On the other hand, the odour of the expectoration, though foetid, was considered to be less so than is usually the case in gangrene.

Dr. Stokes, speaking of the pulmonary gangrene, says, "The only pathognomonic symptom is the extraordinary and disgusting odour of the breath and expectoration. The stench, however, is not constant, for during the progress of a case it may disappear more than once; in some cases the breath is foetid, whilst the expectoration is free from odour."

Laennec states, that in these cases the expectoration is so characteristic "that all these signs" (which he had just enumerated) "would be insufficient without it." He describes it as yellow, ash-grey, verging on green, and of a gangrenous fœtor; or milk-white, gradually becoming greenish-yellow, brown, or ash-coloured, sanious, and purulent. He remarks, "that the fœtor and aspect of the expectoration does not indicate so much the existence of a gangrenous eschar, as a general disposition to gangrene manifested in the mucous secretion of the bronchial tubes."

Andral believes the grey, foetid purulent expectoration to be characteristic of gangrene.

Dr. Williams states, that "fœtor of the breath, and expectoration, is the only physical sign of gangrene of the lung; this" (the fœtor) "may occur, however, in simple bronchitis, and it is only where auscultation has detected signs of pneumonia, that it can be admitted as a proof of the death of a portion of the pulmonary tissue."

It appears, probable, however, that too much value has been attached to this sign: in a diagnostic point of view; for it has been proved by Grisolle, that the grey, or brown, purulent, highly foetid expectoration, may proceed from an abscess; hence cases which have been diagnosticated principally on the strength of this criterion, are as likely to have been instances of abscess as of gangrene.

For the reasons mentioned above, it appeared highly probable, that the case under discussion was one of pneumonia, terminating in abscess of the lung; the subsequent progress of the case, and the additional signs which manifested themselves, tended to confirm this view. The amphoric character of the respiration over the middle and upper part of the lower third of the right side,—the pectoriloquy, gurgling, bottle resonance on percussion,—the extension of the space over which the cavernous respiration was audible,—the appearance of a friction-sound, as if from the approach of the disease towards the surface of the lung,—all these were in unison with the view taken.

The *prognosis* in this case, on the view taken above, could not be favourable. It is true that a very remarkable case of the cicatrization of an extensive pulmonary abscess (verified by subsequent post-mortem examination) is recorded by Dr. Stokes, but this occurred in a strong young man, and probably under other favourable circumstances.

The *treatment* pursued in this case was, first, the exhibition of tartarised antimony, on the supposition of the existence of some pneumonia; this was subsequently discontinued, and a more tonic system adopted; iodide of iron was prescribed, and also morphia, to allay the violence of the cough, and procure sleep: liberal diet was allowed. Nothing more could be attempted than to palliate the symptoms, and this was most effectually done by the morphia. Had the disease been supposed to be one of pulmonary gangrene, perhaps some benefit might have resulted from the exhibition of chloride of lime, wine and opium, as recommended by Dr. Stokes. In a case which occurred under M. Cruveilhier at La Charité, in the spring of last year (diagnosticated principally, if not entirely, by the fœtor of the sputa) a recovery took place under the use of chloride of lime and opium.

The *post-mortem appearances* may be next briefly noticed, principally with reference to the difference between what was disclosed by the autopsy, and what had been anticipated. The right pleura was found to contain upwards of three pints of foetid, turbid serum; the lung was diminished in volume, and adherent at its apex and base; the lower lobe, especially at its posterior part, was found to be gangrenous; no abscess was found, and no tubercle, but the apex of the right lung was firmer and denser than natural.

What evidence was there during life of the existence of a large amount of fluid in the pleura? A considerable part of the liquid was no doubt of recent effusion, but the compression which the lung had undergone, especially in its middle and lower lobes, was adverse to the supposition that the whole had been lately effused. On June 26th, the vocal resonance was remarked to be ægophonic; no importance was attached to this at the time, because bronchophony has often somewhat of the characters of ægophony; but it is possible that a certain amount of liquid existed in the pleura at that time. From July 3d to 6th, a loud friction sound was heard near the situation of the right nipple, excluding the idea of the presence of fluid to any considerable extent. On July 8th, it was remarked that the amphoric respiration, previously distinct upon the lateral surface of the chest, had become feeble, although still heard loudly behind (owing, as was afterwards proved, to the ad-

herence of the lung). At this time the fluid had, no doubt, increased so much in quantity, as to separate the lung to some distance from the lateral walls of the chest. In the early stage of the disease, there was no enlargement of the side, or displacement of the liver; the decubitus was on the healthy side, and the other arguments against the existence of empyema apply equally to the present discussion.

The clear sound elicited by percussion above the right mammary region, may be partially explained by the absence of a corresponding resonant part upon the opposite side, so as to afford a standard of comparison; moreover, the portion of lung which corresponded to this part was the least affected of the whole of the pulmonary tissue.

As already mentioned, no cavity was found in the lung, although all the physical signs observed during life seemed clearly to indicate its existence. This proves, as Dr. Taylor remarked, that cavernous respiration may exist without the presence of a cavity—a fact not distinctly mentioned by writers. Andral states that it is heard only over cavities or dilated bronchi. There must, however, be something peculiar in the condensation of the pulmonary tissue to give rise to it. From the appearances presented in this, and in another case, in which the same phenomenon had been observed, Dr. Taylor supposes that it was owing to the substance of the lung being especially consolidated at one spot; hence the sound of bronchial respiration originating in the tubes is transmitted to the surface with the greatest facility and distinctness by this condensed portion of tissue; the sound is consequently heard louder over this than over the neighbouring parts, and this isolation of the sound conveys the impression of its being produced in a limited spot, and consequently an index of the existence of a cavity.

The sound of *gurgling* was heard in this case: this confirms what has been previously observed, viz. that it is no proof of the existence of a cavity. Andral has observed this, and states that any rhonchus usually originating in a cavity may be produced without one.

Pectoriloquy, also observed in the present instance, has been repeatedly heard where no cavity existed.

The "*cracked-pot sound*" on percussion might perhaps be owing to the presence of a little air in the pleura, generated by some septic process. But as it was only observed three days before the patient's death, when the amphoric respiration had become indistinct laterally from accumulation of fluid, it appears not unlikely to have been due to what Dr. Stokes has remarked, viz. the abrupt termination of the line of dulness pro-

duced by the effusion; for he says, "at this line, particularly in cases of absorption, I have sometimes observed the '*bruit de pot fêlé*.'"

The *abundant purulent expectoration* from the bronchial tubes alone, is worthy of notice. This case also proves that such secretion may take place suddenly, and in large quantity, without the existence of abscess. This has been previously remarked, especially by Dr. Stokes. Again, the amount of the expectoration was influenced by position, just as where there is some excavation,—being greater in the recumbent, less in the erect posture.

Notwithstanding the existence both of the general symptoms, and many of the physical signs indicating the probability of tubercular deposition in the lungs, no tubercles were found after death:—another case, proving the necessity of caution in diagnosing the nature of consolidations of the apices of the lungs. In this case, the condensation of the summit of the right lung was, no doubt, owing to inflammation; the left lung exhibited a specimen of the first stage of pneumonia, which had probably supervened in the last hours of life.

Causes of the gangrene.—In the present case there was tolerable evidence of inflammation having preceded the gangrene, but there was no proof of the existence of intense pneumonia; and this is so far in accordance with general observation. Laennec, who, however, regarded the disease as essentially gangrenous, and regarded the inflammation as a secondary process, describes the symptoms at first as those of slight pneumonia with much depression and anxiety. The invasion is often insidious, and characterised by nothing but general debility. This fact, which was noticed by Frank, is now generally acknowledged. M. Grisolle says, "I have had occasion to see nine or ten cases of pulmonary gangrene, and in no single instance did the disease succeed to a perfectly characterised pneumonia. Of the 305 cases of pneumonia analysed in this work, not one ended in gangrene:—of 70 cases of pulmonary gangrene recorded in the medical journals during the last 25 years, there were at most five which can be fairly pointed to as the sequence of pneumonia." The chances of the occurrence of gangrene are thus in no proportion to the violence of the inflammation; in the cases mentioned, death occurred in seventeen to twenty-four days, a duration which does not indicate any unusual amount of activity in the inflammatory process.

The real cause of the disease in these cases seems to be unknown; the inhalation of some noxious gases has been known to occasion it. Dr. Copland considers that it is doubtful whether it is due to the intensity of the pul-

monary congestion, or to the morbid state of the patient, or both. Dr. Stokes makes a similar observation, and remarks, that in all the cases which he had seen, the patients had been long addicted to the use of spirits. In the case upon which these comments are founded, the patient had been out of health for some time previous to the attack which terminated his existence.

ACESIUS :

A SURVEY OF THE ETHICAL BEARINGS OF
MEDICINE.

By C. F. H. MARX, M.D. &c.

(For the *London Medical Gazette*.)

[Continued from p. 117.]

TO JOHN COAKLEY LETTSON,—
You published a learned discourse on the state of medicine before the Trojan war*. I do not, however, intend this letter for the edification of historians—a class with which you did not identify yourself—but for the thoroughly upright man, which I am led to believe you to have been, from the tenor of your writings at large, and especially from the character of your biography of Fothergill. Such a man is the best in the world to speak with on the import of the history of medicine.

Doubtless you had occasion in life to exercise your acknowledged spirit of charity and toleration, even in larger measure than appears upon the face of any extant record; and I therefore calculate beforehand on your friendly indulgence. You yourself declared, that in the world of phenomena, as in that of sense and of thought, there must be endless variety; as no two leaves can be found on the same tree that are entirely and in all respects alike, and as no one of them can be truly said to be more perfect than another, so is it with human opinions, and also with the conclusions of the heart. You reckoned no fewer than 2000 religious communities†.

You did battle manfully on the side of true medicine against quackery‡, and raised your voice in favour of distinguished merit among the members

of your profession,—of Jenner, for instance, and his vaccination*. Might I venture to express myself figuratively, I should say, that even as you were born in a small islet of the great Atlantic ocean, so had your spirit and your house remained the quiet home of pure humanity amidst the troubled waters of London‡.

Such a man deserves to sit in the general human council of the Amphycitones, as more than the mere man of learning. I, at least, feel myself impelled to turn to you, and communicate with you upon a few points connected with the history of medicine.

Polybius says:—"As a living thing deprived of its eyes becomes useless, so history that is void of truth is a mere useless narrative." But it appears even as difficult to discover what the truth was, and at second-hand, as it is to supply it originally. As the child believes the tale, so does the common reader believe all that historical books contain; the critical inquirer, on the contrary, is content when he meets there with a comprehensive, or even with an entertaining narrative.

In medicine, one would think that it must be least of all difficult to give undisputed or indisputable facts; inasmuch as the business there is not to penetrate the hidden motives of mankind, and to unravel the tangled skeins that interest and passion felt together, but merely to exhibit discovery and special views in their progress. Still, as this narrative is a portion of the spirit of man, so is it dependent on that for its good and its evil properties. The kind of evidence, too, might lead one to anticipate, that in the history of medicine the unquestionable, the positive, would find a place, seeing that even inanimate things bear witness to the facts; for have we not the Memoirs

* Immediately after the House of Commons had passed its vote of £10,000 as a reward to Jenner, for the discovery and propagation of vaccination, Lettson wrote to him as follows: "I was truly chagrined on seeing the niggardly reward voted by the House; and had double that sum been asked, it would have been granted: however, as an individual, I am not disposed to stop here; but immediately to set on foot a subscription that should invite every potentate and person in Europe, America, and Asia, because every avenue of the globe has received, or may receive, your life-preserving discovery. This subscription should not be for you, but it should be a fund the interest of which should be forever devoted to the name of Jenner."—(Baron's Life of Jenner, vol. i. p. 517.)

† Little Van Dyke, near Tortosa.

* History of the Origin of Medicine. London, 4to. 1778.

† Obs. on Religious Persecution. Lond. 1800. Obs. preparatory to the Use of Dr. Mayerbach's Medicines, ib. 1776. The Second Edition, with an Engraving of the Water Doctor from Teniers.

of a Walking-stick, which accompanied many distinguished physicians, one after the other, in their rounds among their patients, and in their own round through life*. All these means and accidents are, nevertheless, no helps or surties for the truth.

Autobiographies, in fact, supply a fair sample of the style in which *authentic* history is compiled. Who so fit to tell the tale of his life as he who has lived it through, as the writer himself, and that all the more certainly when he is universally acknowledged to have been a thoroughly upright man? Is it even legitimate to entertain any doubts in such circumstances?

One of the most sterling medical men with reference to character that ever lived was undoubtedly J. A. H. Reimarus. You remember him, perhaps, as the discoverer of belladonna as a means of widening the pupil of the eye†; and you may even have heard of his father, the rector of Wismar, and author of the celebrated book on the instincts of animals.

Our former colleague, J. A. H. Reimarus, took a great interest, as you did yourself, in all general propositions having reference to the welfare of mankind, and also in useful inventions of every kind. He it was who first thought of contending with the lightning‡; and he was zealous in his denunciations of all prohibitory and restrictive bye-laws in guilds and corporations§; he was incessant in his efforts to make his native Hamburg aware of the advantages at-

tending a liberal and well ordered constitution*.

This blameless man, who says, that not once in the course of his life had he suffered himself to state an untruth even in jest, nevertheless wrote in his 84th year as follows: "The French have been compelled to evacuate Hamburg; I have returned to the desolated, but still my native and freed city, and have been embraced by many friends."

Will not every one believe that all this happened even to the letter as it is narrated? Nevertheless in the postscript of another we find these words: "In his autobiography he saw his return (from Ranzau whither he had retired), as granted to him, and spoke of it as having already taken place. Providence had ordered things otherwise. A friendly hand must here correct the manuscript."

As children to exercise themselves in speech and thought frequently narrate events as having come to pass that never happened, without the most distant purpose to deceive, so do writers sometimes exercise their faculty of writing. The narrative is frequently much less the mature fruit of long and laborious research, composed with a view to compel the suffrages of real judges in such a case, than the hastily conceived and rapidly indited page thrown off to excite surprise, or to make a momentary impression on the mind of the public at large. The historical in this way is brought to approximate the hysterical. The *intaglio* of the accomplished observer and collector is often used by the ready penman for making a cast from in *relief*. His business is to make his work look as much like a foundling hospital as possible, where the parentage of no individual can be known; nevertheless it very commonly shows like an orphan asylum in the end,—it still bears unquestionable evidence, at all events, of the poverty of its immediate origin.

Should the historical chronicle, through want of fidelity, become a scandalous chronicle, it is even with it as with the poison-tree, in which the constituent proximate principles are those of the majority of the most innocuous substances, but where a trifling addition of antihiarine stamps it the deadly upas.

* The Gold-headed Cane, by the late Dr. Mac-michael. 8vo. London, 1828.

† He himself says (Autobiography, Hamb. 1814, p. 33): "An accident by which a quantity of belladonna juice was spirted into the eye and produced a remarkable paralysis or dilatation of the pupil, led me to think that it would be useful to employ the same substance before proceeding to the operation for cataract: the whole extent of the lens is thereby rendered distinct, and the instrument can be guided in the interior with much greater safety." Daries, to whom the accident alluded to happened, made it known in his Inaugural Dissertation, published at Leipzig in 1776.—Vide Baldinger's Sylloge, vol. ii. p. 58.

‡ Von der Blitz-Albeitung, 1768. He says himself: "I showed that the lightning followed the metal for a distance without passing to other bodies." So early as the year 1769 the Jacobithurme, or Jacobsteeple, was provided with a lightning conductor.

§ Inquiries into the presumed necessity of an authorized College of Physicians and a code of Medical Regulations, 1781 (in German). "I hold it not advisable," he says; "determinate rules, and laws forbidding this and that, I believe to have been ever inimical to the progress of knowledge; all powerful remedies have been discovered by chance, or by persons without science."

* Sketch of a Plan of General State Education, Hamb. 1803 (in German).

The superficial and careless historian is not merely guilty of treason to confiding openness; he farther multiplies errors, which are then propagated like hereditary diseases.

Mistrust might very fairly be entertained of every one who before undertaking a general theme for development, had not given evidence by one or several special investigations of his fitness for the more arduous task. One is, in fact, not born, only the poet, the leader, the statesman, and the physician, but also the historian. But no one is invested with power and without more ado—by the grace of God, as it were, like a king; every one must ascertain by painful labour, by resolute effort, whether he be worthy to take a flight above the individualities of life, and have an eye that can grasp existence as a whole.

This, in short, is at the bottom of the fact, that we have no historical lexicon which seizes impressions ever in the spirit of the times in which it is written.

As times change, and men change with them, so also do views and the means of expressing them. The verb "to right" (*berechtigen*, in German) simply signifies "to make the right prevail;" but the word *hinrichten*, which has the same derivative meaning, is now used in Germany when we speak of "putting one to death." In Pliny and Celsus, the word *amylum* implies *fine flour*; in Apicius it is a *sauce*; and with us, at present, it is *starch*. *Water-doctor* was the former title of him who pretended to cure diseases by inspecting the urine; at the present time, the term is applied to him who pretends to cure all diseases by means of water. The rat (*Ratte*, Germ.) was unknown to the Greeks and Romans, but the *Ratz* of the Germans (*Glis esculentus*) they fattened in special establishments (*Gliraria*), and ate. We do not now order balsams externally, pouring them into wounds; we prescribe them internally, to check mucous fluxes of various kinds. To express the highest degree of haste and rapidity, the ancients had but such words as *remis et velis*; but what was the speed attained by Cæsar or Scipio, with all his oars and sails, compared with the flights we now perform in our steam-ships and railway carriages? What infinite pains must not a man

now take to ascertain the species of a plant whose virtues are celebrated by older observers! It is altogether doubtful what the "hyssop that groweth on the wall" was; and Storck's observations on the Monk's-hood, published no longer ago than 1762, only become available for any useful purpose when we know that it is the species *Cammarum* (*Aconitum Cammarum*) which he used.

The historian who keeps pace with the times by means of a chronology, must not only do so in all truthfulness, but also in the right way; for even a decennium will occasionally put him to the test. In the wars of the French revolution the tactics of the Allies were good in themselves, but their strategy was no longer available; the Sansculottes always came off victorious, because they never lost time with the usages of war, about which they cared not a rush. They were not stable in their negotiations, but their deeds were also without duration.

When historical writing proceeds from the inward call to undertake the duty, it is always conceived and executed rather upon grounds of reflection and doctrine than of incident and authority. It is by no means necessary that the writer, to give credibility to his narrative, be dry as pumice, or the sands of the desert.

What truly arouses our souls to sympathy, and excites our interest, is still neither more nor less than the apprehension and exposition of the path by which humanity, whether in its evolution as a whole, or in some particular department of art or science, advances towards the better, the nobler, the more perfect; each step in its inquiries, in its volitions, in its struggles, may be likened to the knots in the stem, which, succeeding one another, and coming closer and closer as we ascend, finally expand in the odorous blossom. The idea of a vital spark pervading and to pervade infinity, fans the flame in our own breast into a glow; whilst the mere spectacle of the faded coverings and members of the past sends a frosty chill to the heart. Even so do the Pyramids, once evidences of active existence around them, now meet the traveller, in the sandy plains of Egypt, like petrified antediluvian trees of the desert. In history, nevertheless, we cannot be satisfied

with a mere display of reflections and outpourings of the heart; it still has need of a broad and firm foundation.

He who has not, led by lofty self-denial, withdrawn himself for years into the quiet of deep and connected study, with a view to immerse himself wholly in his subject, will never produce aught that is independent and original. With the diving-bell of unwearied application he must recover the drowned treasures of ships long sunken; with the Moses' rod of penetrating criticism he must make springs of living water flow from the arid rocks of bygone events.

To draw from original sources is as much as to say that we appropriate the knowledge of the best spirits of times past, that we hold communion with the models and types of literature alone; and whilst we study them on every side, and strive to know them intimately, keep carefully aloof from those who have fashioned themselves only for others. The gleanings of the stubbles is performed by the poor after the harvest has been carried. Indifferent and bad writers are like the mirage of the desert, which, in the distance, looks like a cool lake, but mocks the thirst of him who would draw from it at hand.

Even as little as he is worthy of the name of historian who torments himself with chronicle events, is he deserving of the title of literary historian who collects mere notices of books and old editions. To merit the latter honourable denomination spiritual supremacy over the collected heap is indispensable; independent decision and impartiality to other natures must have been attained. Between him who writes the despatch and him who copies it out, there is a vast difference.

All the world knows that since the appearance of Asiatic cholera, in 1817, hundreds of pamphlets and larger works have seen the light on the subject, few of which promise to meet the requirement of Thucydides, and prove "possessions for eternity." With reference to this subject we already begin to be like those who, after the lapse of centuries, collect the scattered and disjointed fragments of an author: we see that in the multitude of writings, the number that convey any clear conception of the disease, any authentic information of its nature, or that would

prove a safe guide to us, should the pestilence recur, is wonderfully small.

According to the axiom: "*Quisquis præsinitur bonus*," every one who shows himself in types is currently allowed, in the world of books, to be honest. Nevertheless, the truly scrupulous writer—I mean morally scrupulous—he who never allows himself to disguise and appropriate the goods of others, is by no means one of the common phenomena. This led Cuvier* to quote it as an instance of magnanimity in Corvisart†, that he had produced Avenbrugger's work on Percussion as a translation, and not appropriated the matter, and published it to his countrymen as his own!

The writings of him whose sole purpose it is to be named, without regard to the intrinsic value of his production, may be appropriately compared to the broccoli in Rome during the winter season, which smells of the dung with which the gardener, reckless of all but the appearance of the vegetable, has forced it.

To be capable oneself is even as indispensable as conscientiously to admit, and openly to honour, capacity in others. There seems no occasion, however, to go the length of that old maxim which says, "Into the spring from which thou hast drunk thou shalt not cast a stone." We ought to be ready, on the contrary, to express our inward thankfulness for the good we have received from a new thought encountered, from a noble feeling aroused, and bear cheerful witness, both in inclination and in act, to its author for the debt of gratitude and respect we owe him‡.

* Cuvier, *Eloges Hist.* t. iii. p. 372: "La forme donnée à cet ouvrage doit être remarquée comme la preuve d'une noble générosité. M. Corvisart y immolait sa gloire."

† Corvisart, in his translation, takes the same credit to himself, he says: "Je pouvais sacrifier le nom d'Avenbrugger à une propre vanité; je ne l'ai pas voulu; c'est lui, c'est sa belle et légitime découverte que je veux faire revivre."

‡ Walter S. Landor (*Imaginary Conversations*, &c. 8vo. London, 1826, vol. i. p. 74), expresses himself beautifully on this point: "If the ear is satisfied; if at one moment a tumult is aroused in the breast, and tranquillized at another, with a perfect consciousness of equal power exerted in both cases; if we rise up from the perusal of the work with a strong excitement to thought, to imagination, to sensibility; above all, if we sat down with some propensities towards evil, and walk away with much stronger toward good, in the midst of a world, which we never had entered, and of which we never had dreamed before, shall we perversely put on again the old man of criti-

Every medical writer, you will grant me, is already an historian to the extent that he must look into the history of the disease of which he writes, and of the treatment which has been proposed for it: out of the past he apprehends the present; out of numerous foregone particulars, he must compose for himself an image of that which is. But he also knows better than any one else that the *opera omnia* of a man are not the best of him; there is mostly much that cannot be too speedily put away and forgotten. Many, in their desire to have a complete biographical record, show themselves eager to collect every relique of the earliest infancy, even to the dried navel-string of the great man,—this genuine incunabula,—as if from such mummies of the first years or days of life the character and purposes of the accomplished man could be interpreted!

It is by the same spirit of pious regard of the antique that the editors of celebrated works are oftentimes actuated, when they collect and publish every scrap of paper left by their author. They do not reflect that, with regard to contents, such “complete editions” are incomplete, even because they destroy the general estimate which we had been led to form of the author's mind and influence; they render indefinite and hazy what was well-defined and clear before.

To escape personality in this my epistle to you, I have striven to avoid every approach to contemporary allusions, and fear thereby almost to have become obscure.

But as, in the land of shadows you now inhabit, you in all probability have our literary movements presented to you as in a camera obscura, you will doubtless be able to perceive at a passing glance what the weak son of earth can scarcely comprehend with the utmost straining both of his spiritual and corporeal eyes.

cism, and deny that we have been conducted by a most beneficent and most potent genius? Nothing proves to me so manifestly in what a pestiferous condition are its lazarettes, as when I observe how little has been objected against those who have substituted words for things, and how much against those who have reinstated things for words.”

[To be continued.]

RESEARCHES ON GOUT.

By ALEXANDER URE,

Fellow of the Royal College of Surgeons of England, and Surgeon to the Westminster General Dispensary.

(For the *London Medical Gazette*.)

It has been uniformly observed that persons who indulge habitually in the use of animal food and fermented drinks, and lead at the same time an irregular, sedentary, inactive life, are prone to gout. A morbid plethora supervenes which gives rise to undue tension of the arterial system. The blood is loaded with nitrogenized principles and calcareous salts, and if the kidneys and skin fail in removing these from the system, they are sooner or later deposited upon the synovial membranes and the tendons, or within the arterial walls; in the former as urate of soda, in the latter as phosphate of lime.

The renal secretion is found to deviate more or less from the natural standard. It would appear from the researches of Frommherz and Gugert, that for some time before a fit of gout it contains no uric acid; whereas it is well known that at other periods there is generally a superabundance, so much so, that the urine of gouty subjects is remarkable for holding in suspension and throwing down that acid in the crystalline form. M. Rayer points particular attention to this fact, and a recent opportunity of verifying it was afforded me in the instance of a gentleman, who came from Florence to consult me by desire of Prof. Targioni, of that city. His urine, though pale in colour, and of the low density of 1.015, spontaneously deposited upon the sides of a glass tube, when cold, abundant lozenge-shaped crystals of uric acid. Yet this gentleman, not long previously, had undergone a regular course of the Vichy waters.

If, then, it be assumed that from occasional causes the uric acid be pent up and allowed to circulate with the blood, urate of soda will undoubtedly form. This I ascertained by the following line of research. A certain quantity of the fresh serum of human blood was set to digest in contact with a given weight of uric acid at the temperature of the living body, during two hours. It was then filtered. To the

clear filtered alkaline liquid when cold, a few drops of very dilute muriatic acid were added, whereupon a cloud of white shining particles immediately began to fall down, which proved upon microscopic examination to be well-defined crystals of uric acid. It may be observed that the same dilute acid when added to the pure serum of the blood rendered it unusually limpid. Hence it was evident that some of the uric acid had been taken up and combined with the alkaline albuminate present in the serum.

On repeating the experiment at a higher temperature, the filtered serum, when diluted with water, afforded by the next morning a cloud of glistening particles, which, viewed by the microscope, were seen to be fan-like groups of acicular crystals of urate of soda, as here figured.

These after a while coalesced into little granular masses, resembling those of chalk stones.

Some white tophaceous particles, taken from the last joint of the finger of a gentleman who died of gout, and for which I was indebted to Mr. White, of Westminster Hospital, yielded after being dissolved in hot distilled water a crystalline precipitate identical in form with the preceding.

Further, on adding uric acid to a warm solution of tribasic phosphate of soda (the essential basic alkaline salt of the blood, according to Enderlin, *Annales der Chemie u. Pharm.* Bd. xlix. p. 317) fan-like tufts precisely similar in appearance to the above were obtained.

There can be, therefore, no question as to the possibility of uric acid being converted into urate of soda, through the medium of the serum of the blood, and that at the ordinary temperature of the human body.

It has been conceived that many of the phenomena of gout depend upon a depraved condition of the blood induced by intermixture with the above salt. This view seems the more

plausible, when we call to mind that one form of gangrene, the senile, mostly attacks persons who have previously been gouty, or have led a life of luxury and indolence, and whose system has most likely been generating uric acid in excess; while another somewhat congenerous form of gangrene is met with in individuals, in whose body a slow but mortal poison has been at work, called *ergotine*, consequent upon the prolonged use of bread containing spurred rye. Both of these pathological conditions, however, are connected more or less directly with arterial inflammation, and to that we must look as the predisposing cause. Still, it cannot be denied that the primary irritant source in the former instance may have been urate of soda, in the latter *ergotine*.

Upon perusing an elaborate memoir on chronic arteritis, by the venerable Professor Tommasini, of Parma, published in a late number of the *Annales de Thérapeutique*, it will be seen that many anomalous symptoms characteristic of confirmed gout, are those of inflammation of the abdominal aorta. Thus it is stated that patients who died of that disease alone, complained of flatulence, frequent eructations, sense of pain and uneasiness referred to the epigastrium, besides other dyspeptic and nervous symptoms, more or less akin to those of hypochondria. Might not these facts assist in elucidating some of the rapidly fatal seizures of what is called gout in the stomach, where no trace of disease has been found in that organ after death?

Again, admitting with Prof. Tiedemann that calcareous incrustation is the sequel of arterial inflammation, abundant evidence is to be found recorded by Stoll, Selle, Lettsom, Michaelis, Kreysig, Corvisart, Lobstein, and Hope, illustrating the formation of earthy deposits in the walls of arteries and valves of the heart in gouty subjects.

In articular gout, tophaceous deposition occurs for the most part in the smaller joints, especially such as are exposed to much friction and pressure, as the metatarso-phalangeal and the distal articulation of the great toe. But no part or structure of the motor apparatus is exempt. In a case that recently presented itself to me it existed in the cartilage of the ear.

It has been generally recognised that the same morbid condition which involves an increased formation of uric acid is attended with defective secretory action of the liver. Hence it has been found that whatever stimulates the excretory duct of that viscus, and determines thereby a more or less free discharge from the biliary pores, checks the above formation, and exercises a salutary influence in the gouty habit. Accordingly, Hippocrates advised that purging should be resorted to upon the first motion of the humour in gout. From a thorough conviction of the importance of this principle, I am solicitous to direct attention to a remedial agent which seems to exercise a specific influence over the hepatic function. This is the sulphate of manganese, a neutral salt, whose properties I was led to investigate at the suggestion of Dr. Pereira. Manganese, in the state of proto-carbonate, is present in the waters of Marienbad, Carlsbad, and other German springs, whither gouty invalids annually resort in quest of health; in the state of oxide, it forms one of the normal constituents of the bones. It was first shown by M. C. G. Gmelin, of Tübingen (*Versuche über die Wirkungen des Baryts, &c.* 1824, p. 96), that the manganese salts when injected into the blood-vessels augmented the biliary secretion to such a degree as to produce a deep yellow staining of the coats of the intestines, and of the great vessels in the vicinity. According to M. A. Barbet, (*Journal de Chimie Médicale*, tom. v. p. 534) muriate of manganese forms a main ingredient of a nostrum sold in Paris, under the name of the decostruent powder of Rouvière. This, taken for a few days, is said to procure abundant bilious evacuations.

If a drachm of sulphate of manganese be dissolved in about half a pint of water, and swallowed before breakfast, it will generally occasion after the lapse of an hour or so one or more liquid stools. With the view of testing whether bile was thus discharged to any amount, a portion of the loose feculent matter was digested with strong alcohol, in order to separate the mucus, and thrown upon a filter; a limpid olive-coloured solution was obtained, which after evaporation by a water-bath to the consistence of honey, yielded with the addition of boiling

muriatic acid, a notable quantity of biliary resin, together with a little fatty matter. Thus, unequivocal proof was afforded of the excretion of bile.

Thus salt may be therefore reckoned essentially *cholagogue*, in the strict sense of the word. Its action is prompt, and soon over, nor does it produce any of those distressing and lowering effects which are so apt to follow the exhibition of mercury and antimony in certain constitutions. A retired navy surgeon, labouring under a feeling of weight and tenderness in the region of the liver, dragging sensations referred to the right shoulder, uneasiness about the epigastrium, dull headache, want of appetite, and paleness of the alvine evacuations, afraid to have recourse to mercurial preparations, took by my recommendation the above salt in moderate doses, at intervals during three weeks. The result was complete removal of the preceding symptoms, and restoration to permanent health.

Sulphate of manganese has a cooling and bitter taste, resembling that of Glauber salt. Dr. Thomson (*Chemistry of Inorganic Bodies*, vol. ii. p. 587) says, "it may be administered as a cathartic, in doses of from half an ounce to an ounce." I have always found a much smaller quantity suffice, and should be reluctant to give it to that extent. It acts most efficiently when dissolved in a considerable quantity of water. On particular occasions infusion of senna furnishes a useful adjunct.

I forbear touching upon colchicum. That potent drug we are told suppresses but does not cure gout, and when long continued inflicts serious injury upon the constitution. In many instances it would appear to act as a slow poison. If, indeed, as Sir B. C. Brodie alleges, it stops the biliary secretion, its protracted use must be fraught with mischief. It ought therefore only to be exhibited in urgent cases, and that sparingly.

In order to abate the erethism of the vessels of the gouty circulation, to further the absorption of effused fluids, and to arrest the recurrence of attacks, which, in the long run, lead to distortion and ankylosis, the topical employment of acetic ether and rectified coal naphtha will be found highly serviceable. The former was first introduced to the notice of the profession by M. Sedillot, in the Transactions of the Medical Society

of Paris, (No. x. *Mess. An.* 5) but never seems to have attracted attention here. Acetic ether generally determines a speedy sedative agency in the more acute stage of the malady, when applied with gentle friction over the whole of the affected surface to the amount of half an ounce every twelve hours, provided after each friction the patient is kept warm in bed. In the sub-acute form of the disease, I have witnessed very beneficial effects from simply pencilling over the part with a camel-hair brush dipped in naphtha*. In some instances, indeed, this seemed to have the power of warding off an impending paroxysm. I was first led to try it in gouty cases, from being told by an extensive manufacturer of the article near Birmingham, that affections of the joints were unknown among his workmen, while they were common enough among the operatives of other factories in the neighbourhood.

Coal naphtha is a pure hydro-carbon, almost identical in nature and properties with the naphtha which occurs native on the shores of the Caspian sea, in Persia, and other countries of Asia. The latter, alluded to by Herodotus, has been used from a remote period by some of the nations of the east, against the very ailment in question. Thus, Dioscorides (*Lib. i. c. 85*) says, "*podagris articolorum doloribus lethargisque prodest*"; and Bontius (*Hist. Nat. p. 17*) in describing what he calls "a noble species of naphtha" brought from Sumatra, and highly prized for its medicinal virtues by the Javanese, concludes as follows: "*partibus affectis illitum miraculi instar aegros consolatur.*"

Naphtha topically applied imparts a feeling of warmth, sometimes accompanied with slight tingling. It acts obviously upon the principle of a mild but penetrating counter-stimulant, determining contraction of the capillaries, increase in the rapidity of their circulation, and progressive absorption of liquid effusion. As such, its use is of course contra-indicated whenever there is general excitement of the vascular and nervous system. The influence of counter-irritation over gout was amply demonstrated, though in a rather severe manner, by Sir William Temple, on his

own person, nearly two centuries ago. That distinguished statesman, who pithily designated "gout a companion that ought to be treated like an enemy, and by no means like a friend," heroically applied the Chinese moxa to his foot, and thereby got permanently cured (*Essay upon the Cure of Gout by Moxa, 1677. Works, vol. i. p. 134*). His account of the disease is given with nosological precision, and nothing can be more graphic than the detail of what he felt while the burning cone was in contact with the skin.

Among other local applications from which occasional advantage has been derived, may be enumerated tincture of arnica, and an ointment composed of one part of extract of belladonna, incorporated with eight or ten parts of cerate. Poultices are objectionable because they relax the capillaries.

After extensive experience in the employment of naphtha, I can confidently assert that no instance has ever presented itself of the slightest tendency to what is called "gouty metastasis," that is, the translation or removal of the disease from the extremities of the body to some internal part or organ. It need scarcely be observed that all outward means, to be availing, must be aided by appropriate hygienic and therapeutic measures.

In order to get rid of the œdema which usually supervenes after a fit of articular gout, it is advisable to support the limb in a position considerably elevated above the level of the body, so as to favour the ascending circulation. By this procedure absorption is facilitated. The support, to be efficient, however, ought to be steadily maintained both night and day. Although rather irksome at first, patients soon become habituated to it. An oblong deal box, having the sides a little elevated and sloping, with belts slung across, will be found to answer the above purpose.

As a remedial agent, seemingly endowed with qualities capable of counteracting and removing tophaceous deposition, silicate of potash, the *liquor of flints* of the older chemists deserves a trial. This salt passes through the system unchanged, and can be detected in the urine of animals to which it has been given by the mouth. It exercises a very powerful solvent action upon the urate of soda.

* Care must be had not to confound this with a spirit sold under the same name, used for making hatters' varnish, and lately introduced as a medicine. The properties of the two are quite dissimilar.

I have prescribed it for one or two patients in doses of ten and fifteen grains twice a day, dissolved in six or eight ounces of water, with apparent benefit.

The efficacy of the benzoic preparations in controlling phosphatic deposition, to which gouty people are likewise prone, was shown by me in a paper published in the *MEDICAL GAZETTE* of February 1843; and it, as Professor Liebig states (*Lancet*, June 8, 1844), "the larger the amount of soda which combines with these acids," alluding to the sulphuric and hippuric, "the less comes to the share of the uric acid," it may be inferred that the administration of benzoic acid, will, in consequence of the surplus production of hippurate of soda, necessarily tend to supersede any inordinate formation of urate of soda.

In reference to the surgical treatment of gouty deposition, it may be suggested that when this is unconnected with the articulation, has a pulpy feel, is augmenting in size, distending the cellular texture and skin, and causing inconvenience and deformity, a small subcutaneous puncture may be made with a tenotome at a few lines distance from the tumor, and its pultaceous contents slowly pressed out. If left to itself the concrete mass eventually undermines and ulcerates the integuments, and is expelled amid a more or less profuse suppuration. Under such circumstances emollient poultices ought to be assiduously applied, and the exposed surface freely touched with nitrate of silver. This salt possesses the property of decomposing and disintegrating both the urate of soda and phosphate of lime.

Where, as frequently happens, the ulcerated opening remains fistulous, and gives issue at intervals to chalky-looking fragments, the nitrate of silver may be employed in solution. Sometimes it is the articulations themselves which furnish the tophaceous matter; here no interference is called for, since little or no annoyance ensues, owing to the changes which the constituent parts have undergone.

The following cases will, it is hoped, serve to illustrate some of the principles above laid down.

M. Casey, aged 60, of wan aspect and impaired constitution, while going down stairs upon the 16th of Feb. 1844, missed the step and fell down. The consequence was fracture of the fibula

between three and four inches above the ankle. He came under my care the following day, at the Institution in Gerrard Street, and the limb was put up in splints and bandages in the usual manner.

In the course of twenty-four hours afterwards, he was attacked in the night with severe gout in the foot, the pain extending from the toe up to the knee—a disease under which he had laboured for the last fifteen years. He had from the resident medical officer a colchicum mixture, which produced violent disorder of the stomach, and no relief to the pain. I subsequently ordered some aperient medicine, together with an embrocation of naphtha, by the joint use of which the gouty symptoms were soon mitigated. Progressive union and consolidation of the broken ends of the bone ensued, and after the lapse of a couple of months from the receipt of the injury he was able to move about. That leg is now quite as firm as the other.

The above case furnishes an example of latent gout, roused into activity through an external cause. The disease, however, soon yielded to remedial means, and did not prevent solid ossific union eventually taking place. It may be added that this man has since been threatened with a return of his old ailment, but has uniformly succeeded in keeping it at bay by the timely use of naphtha.

W. Emmett, aged 35, of robust make and sanguine temperament, accustomed to partake freely of animal food and fermented liquors, was admitted under me upon the 27th of May, 1844. Four days previously he was suddenly attacked with pain and swelling of the left knee-joint, accompanied with a distressing feeling of tension and contraction in the tendons of the inner ham-string muscles. When I saw him, the knee was much swollen, and rather tense; it was hot and painful on motion, and there was a reddish blush over the surface. Pressure at the outside of the patella occasioned acute pain. The pulse, skin, and urine, were natural. He had been taking opening medicine. As he peremptorily refused to submit to any local abstraction of blood, or to blistering, and as I ascertained that for the last eight years he had been visited with repeated fits of gout, a disease with which his father and grandfather

had been afflicted, I directed the assiduous application of naphtha.

The use of the embrocation was followed by rapid subsidence of pain, stiffness, and swelling. Is able to walk about to-day without the aid of a staff to lean upon, as formerly. He now complains of swelling and pain of the right wrist-joint, impeding the use of the hand, and which came on unexpectedly in the course of the night. To apply the naphtha to the wrist.

June 1.—Can move his wrist and hand with perfect freedom; the swelling is gone. Says that he felt marked relief after the second time he used the naphtha. There still remained a little stiffness of the knee-joint, which, however, gradually went away without any other treatment.

We have here gout in one of its protean forms, simulating that which under other conditions might have proved a very troublesome affection of the synovial membrane of the knee-joint. Nothing could be more decisive than the effect of naphtha in arresting its progress.

David Reid, aged 53, of short stature, sallow complexion, and emaciated frame, applied to me upon the 11th of June, 1844, under the following circumstances. Complaints of continual pain in right hand, with feeling of heaviness, and also of scalding when touched. There is considerable swelling of the wrist and knuckle. Over the distal extremity of the metacarpal bone is a flat indurated concretion beneath the skin, of the bigness of a French bean, of twenty years' standing. Another tumor, about the size of an almond, occupies the site of the bursa over the olecranon of the arm of the same side, of more recent date.

His appetite is bad; he is languid, listless, and dejected, frequently yawning and sighing; he suffers from flatulence; a wiry vibratile pulsation can be felt in the different arteries of the hand and wrist; the neighbouring veins are much dilated; pulse 80; there is no undue action of the heart; urine is albuminous, of sp. gr. 1.013; pale in colour, deficient in uric acid, but showing a faint acid reaction with litmus; bowels slow.

States that he has been constantly tormented with gout flying about him during the last four months—a disease

to which he has been liable for a period of thirty years; has six brothers, five of whom have been likewise afflicted; is ignorant whether his parents were so; is a shoemaker by trade, and formerly drank largely of gin; has taken so much colchicum at one time and another, that the drug has lost all power in alleviating the disease; it only produces faintness.

Notwithstanding the exhibition of various aperients, diaphoretics, and anodynes, conjoined with the frequent application of naphtha, no distinct amendment ensued till a fortnight had expired. The urine throughout maintained its albuminous character, and its low density, ranging from 1.009 to 1.013. The subsidence of the pain and heat of the gouty articulations was followed by some oedema of the feet and ankles of about a week's duration.

June 26.—He was ordered tencrains of silicate of potash, dissolved in half a pint of water, twice a day.

July 16.—Experienced a febrile attack, attended with painful tension, swelling, and redness of left hand, elbow, and shoulder. To apply acetic ether with friction, and to take a pill containing scammony and jalap.

I saw him again at 9 o'clock, p.m. The ether had promptly abated the pain and tension; the hand now pitted on pressure; the bowels had been freely moved; next day he was convalescent.

22d.—Called to say he feels in better health than he has done for several months. Thinks there is a sensible reduction in the bulk of the chalk stones since taking the silicate of potash; his urine remains unchanged. To take a teaspoonful of sulphur every morning.

We have here an instance of the "lapidosa chiragra," associated with albuminaria; a state of things in which colchicum is highly prejudicial. The intractable nature of the attack may be ascribed to decay of constitution through intemperance and organic disease. The congestion of the veins, which Baglivi reckons a certain precursor of gout, and always persisting during the fit (Barthez, C. I. lib. i.), so conspicuous in this case, is regarded by M. Rognetta as one of the phenomena peculiar to the angioïtis which constitutes the dynamic condition of that malady. Taken

in connexion with the hypochondriac symptoms already enumerated, it would seem to indicate some deep-seated arterial lesion. It deserves notice that under the use of the silicate of potash there was apparent diminution of the tophus.

John Coleman, aged 50, seaman, of short stature, robust make, and active habits, wont to eat freely, but not given to excess in drinking, admitted 21st of June, 1844; complains of racking and gnawing pain in ball and first phalanx of great toe of right foot, which are red and swollen; walks very lame in consequence. Has been tormented in this way during the past fortnight, but last night the pain became so aggravated as to prevent his sleeping; pulse 72, rather hard; skin soft and moist; tongue clean; bowels confined; urine not examined. Had a similar attack last summer, affecting both great toes for the first time; his general health is excellent, excepting at the periods in question; is troubled with flatulence; there is no proof of hereditary tendency; has been taking Epsom salts, and used fomentations.

Ordered Naphtha as an embrocation, and five grs. of blue pill, with five of extract of Colocynth, every night.

June 26.—Says that he feels immediate relief, enduring for four or five hours, after each application of naphtha, and is in all respects better; the redness and swelling are much lessened; sleeps the greater part of the night.

Ordered, of Sulph. of Manganese, 5j.

28th.—The manganese salt acted powerfully, producing a marked beneficial effect in the course of four hours; the swelling and redness are quite gone; no tenderness remains, so that he can walk about in a strong leather shoe; says that he derived such speedy and sure relief from the naphtha, that whenever he perceived any threatening of nocturnal pain, he immediately pencilled over the part in bed, which enabled him to enjoy a sound sleep.

To continue the use of the Naphtha, and to swallow a full dose of Sulphate of Manganese every morning.

He went on taking the manganese salt in moderate doses every morning till the 3d of July, when he was dismissed cured. He applied again as a patient upon the 12th of the month,

complaining of pain and swelling in both of his great toes, which he ascribes to having imprudently eaten a heavy supper and drank a quantity of beer. By resorting to the employment of sulphate of manganese and naphtha, he got well in a week. He was directed to take for a while a teaspoonful of sulphur daily.

This man was of a bilious temperament, and notwithstanding the free exhibition of blue pill and colocynth, no satisfactory remission of his symptoms took place, until the excretory function of the liver had been well stimulated by the sulphate of manganese. The naphtha had a very happy effect in abating the pain and erythematous redness. Habitual indulgence in the use of London beer is very apt to engender gout; the quantity of acetic acid and gluten that beverage contains being prone to sour the stomach and disorder digestion.

Mr. E—, aged 39, short and thick-set, consulted me upon the 9th of Oct. for an attack of gout in the left foot, which had come on suddenly four days before. The back of the foot was swollen; the skin presented a pale rosy blush, and the muscles and tendons were so exquisitely tender, that in order to get from one room into another, he was compelled from want of crutches to crawl on all fours. There was heat of surface; pulse 96; tongue clean; urine not examined; prior to my visit he had been taking saline aperients and colchicum.

His father suffered from gout, and he has had some seven or eight attacks at various times; never knew colchicum fail in relieving him before. Has abstained wholly from fermented drinks during the last four years, having joined that rigid Temperance sect, the Rechabites, but eats heartily, and takes but little exercise.

Ordered to apply Acetic Ether.

By the next day all pain and redness had vanished; there remained only some swelling and stiffness of the foot, for which the naphtha was recommended, and as he had some symptoms of biliary derangement, a dose of sulphate of manganese was prescribed. These served to dispel every vestige of the attack. Shortly after, he had a seizure in the ball of the great toe of the other foot, for which he treated himself.

This case exemplifies the utility of acetic ether in the first stage, and of naphtha in the sequel, for subduing the local affection. One drachm of sulphate of manganese acted here as an emeto-cathartic and diaphoretic, and seemed to remove a considerable amount of general oppression of the system.

For the next case, dated Feb. 1843, I am indebted to the patient's brother, a physician of eminence, and for many years attached to a county hospital.

"Mr. J. S——, aged 56, short stature, robust figure, florid complexion, nervous-sanguine temperament; habits of life active; habits of living not particularly temperate.

"About ten years since first experienced an attack of gout, whilst in a distant colony, the Mauritius, where for ten years previously he had been accustomed to a free course of living, drinking freely of French wines, and indulging also occasionally in brandy and water. Has never indulged otherwise in the pleasures of the table; nor am I aware that he has any hereditary predisposition to the disease.

"Gout first showed itself in the ball of the great toe, and has never been attended by much disturbance of the stomach and bowels. The attacks have been very severe, though of short duration, and in general he has experienced about four of them during the year; some of the larger joints have of late been subject to them, especially the shoulders and elbows.

"The usual practice which has been pursued in his case has been the exhibition of purgatives with colchicum in the first instance, followed by salines and colchicum in more divided doses, using also tepid evaporating lotions, with occasional anodyne embrocations. Since using a naphtha embrocation, prescribed by Mr. Ure, about twelve months since, and which he was directed to apply at the commencement of an attack of pain, he has invariably succeeded in cutting it short, so that he has had no regular attack of gout within that period. His general health appears to be at present better than it has been for several years, nor has he been subject to any attack of headache, or of uneasiness in any other internal organ."

13, Charlotte Street, Bedford Square,
Nov. 1844.

ON THE NATURE AND SEAT OF HOOPING COUGH*.

By J. S. STREETER,

One of the Presidents of the Physical Society of
Guy's Hospital.

(For the Medical Gazette.)

IN the paper of this evening, I propose to bring before the Society one particular subject for discussion connected with whooping cough, rather than attempting a general essay on the complaint. The adoption of such a limit seemed absolutely necessary in order not to exceed the time usually allotted for papers, and to avoid the necessity of entering into a detailed account of the many important and protean complications with which the simple disease is so often encountered in practice.

The subject which I have chosen with the hope of contributing somewhat to the elucidation of this extraordinary complaint, is the nature and seat of the disease. As every theory advanced or advocated requires to be tested by its adequacy to explain the phenomena observable in the disease by its morbid anatomy, and by the effect of remedies which enjoy popular or professional reputation in its treatment, I trust the subject will not be without sufficient practical interest to elicit discussion, and justify its introduction here.

Before my present audience any extended description of the symptoms, progress, duration, and terminations of so common and familiar an affection, would be misplaced and superfluous. For the immediate purpose of this paper it will be only requisite to remind them that the symptoms of the simple uncomplicated disease are divisible into two stages.

1st. The *catarrhal*, marked essentially by irritative and dry cough, somewhat sharper perhaps, but never absolutely distinguishable from that of an ordinary or an influenza catarrh. This stage is ushered in by more or less fever, usually not very noticeable in a child; but in the adult, as far as my observation and inquiry have extended, the headache and general oppression have been rather severe than otherwise.

The 2d, or *hooping stage*, which

* Read before the Physical Society of Guy's Hospital, Dr. G. O. Rees in the chair, November 2, 1844.

seldom commences before the second or third week, is marked by the peculiar convulsive cough, whose paroxysms distinguish and give name to the disease. Each paroxysm of cough is always terminated by the expulsion of mucus from the air passages by the act of expectoration or vomiting, or by a combination of both these processes. After the expulsion of this mucus the mechanical disturbance of the respiration and circulation occasioned by the coughing gradually subsides, and these important functions resume their ordinary and normal state until they are again disturbed by the access of another paroxysm.

On analysing the paroxysm it will be found that it commences with forcible and progressively shortening efforts of expiration, which succeed each other with great rapidity, during which the lungs become as far as possible exhausted of air, till at length they are suddenly replenished by a deep, forcible, and partly spasmodic inspiration, which completely fills every air-cell. During this inspiration the peculiar sound — the hoop — takes place, and is obviously caused by the inward rush of the air through a partially and spasmodically closed glottis, which no act of the will can imitate. The number of expiratory efforts which precede the deep inspiration is greater in the young subject than in the adult, and produces some modification in the character of the hoop.

Each paroxysm of coughing is preceded by a tickling or pricking sensation experienced at the lower parts of the trachea, which gives warning of the approaching fit. This premonitory sensation produces the inquietude and alarm observable in the very young just before the paroxysm, and induces the older to secure the most favourable position for the expulsion of the abnormally saline secretion that is formed by the catarrhal affection of the bronchi which constitutes the disease, and which saline mucus, by its presence in the larynx, where it acts precisely as a foreign body on the sensitive membrane, I regard as the true and exciting cause of the suffocative paroxysms of the second stage.

Before concluding this sketch of the simple uncomplicated disease, it may be well to add that it appears to me unquestionably contagious, and that it

usually attacks only once during life. To the latter circumstance, however, as in the case of the exanthematous fevers, there are occasional and not very unfrequent exceptions. Its occurrence at the adult age is, I believe, less uncommon than is generally imagined, for I am personally acquainted with many adults who have been visited by the disease; among these my brother, who experienced a second attack in the 44th year of his age.

The authors who have noticed or written especially upon this disease, like the names that have been assigned to it, are many. Dr. Forbes, in the Medical Bibliography attached to the Cyclopædia of Practical Medicine, has enumerated no less than fifty-five, while the estimable author of the Dictionary of Practical Medicine—a veritable Hercules in Æsculapian Researches—has filled more than two columns with minion type in enumerating the names of writers on it, and the mere titles of their works. “Tot homines, tot sententiæ,” says the proverb, and, as might be expected, great diversity of opinion has been entertained on the precise nature and seat of the disease. For an abstract of these views I refer to the able works I have just mentioned, and to the special treatises of Dr. Watt and Dr. Hamilton Roe, the only ones with which I am at all familiar.

The opinions advanced by most of these writers seem, for the most part, to be reducible to a few general heads. 1st. That which regards hooping cough as essentially a *spasmodic affection of the air passages* arising from a primary irritation, inflammatory or nervous, of the brain, or of one set or more of the respiratory nerves. This theory is advocated and variously modified in the opinions advanced by Hoffman, Cullen, Hufeland, Jäger, Leroy, Löbenstein, Glibert, Breschet, Webster, and Copland.

Dr. Webster considers the affection of the respiratory organs as secondary, and dependent on a primary irritation, inflammatory in its nature, of the brain or its membranes, or both combined. Most of the advocates, however, of the nervous theory, from Hoffman down to Copland, regard the pneumo-gastric nerves as the primary seat of the affection; but others, as Jaher, Löbenstein, and Leroy, locate the irritation in the phrenic nerves.

Others, again, as M. Blache and Dr. Hamilton Roe, place the nervous affection in both the mucous membrane of the bronchi and in the pneumo-gastric nerves. With this opinion, Albert of Bremen, Pinel, and also Laennec, according to the statement of Dr. Roe, substantially coincide.

2d. That which considers the disease as an inflammatory affection of some part of the mucous membrane of the air passages; an opinion which numbers among its advocates the names of Darwin, Watt, Alcock, Dewees, Dawson, Marcus, Guersent, Broussais, Rostan and Dugès, and in support of which, that of the immortal Laennec, is quoted by Dr. Johnson, in his excellent article in the *Cyclopædia of Practical Medicine*,

Dr. Watt believes it "in all cases an inflammatory disease, whose chief seat is in the mucous membrane of the larynx, trachea, bronchi, and air-cells, possibly attended with a minute exanthematous eruption there. He considers that when mild this inflammation runs its course without materially disturbing the other functions of the body, or even the functions of that very membrane in which it is seated, and that whenever whooping-cough proves dangerous or fatal, it becomes so by the degree of inflammation in the natural seat of the disease, or by that inflammation extending or being translated to other parts." Most advocates, however, of the inflammatory origin of the disease, limit the inflammation to the trachea and bronchi, except Dawson, who confines its first seat to the membrane of the larynx, or strictly speaking to that of the glottis—an opinion, by the way, not widely differing from that of Astruc, who of old describes it as "an inflammation of the superior part of the larynx and pharynx."

3d. That which views the complaint as at first inflammatory and afterwards spasmodic. This opinion has been principally advocated by Desruelles, and adopted by Dr. C. Johnson. Desruelles makes the disease consist in a primary inflammation of the bronchi, complicated with a consecutive cerebral irritation, which by its influence over the diaphragm and respiratory muscles, and over those of the glottis and larynx, changes the simple cough of bronchitis into one of a convulsive character.

4th. That which refers the disease, or at least the production of the peculiar paroxysms of the second stage, to a physical or chemical irritant introduced within the larynx, whether applied from without or after it has been engendered in the blood, or in the secretion of the respiratory organs themselves.

Under this head may be arranged the opinion of Linnæus, who referred it to the presence of minute insects in the air; that of Sydenham, who imputed it to a subtle and irritating vapour in the blood which affected the lungs; that of Boëhrne, and also partially that of Rosenstein, who ascribe it to a peculiar miasm acting chiefly on the nerves; but it is the opinion originated by Dr. Bland, of the Hospital Beaucaire, that I wish to place prominently before the Society, because it is the theory, which my experience leads me, with only a slight modification, to adopt as the one most consistent with the phenomena observable in the symptoms, pathology, and successful treatment of the disease. It was originally published in the *Révue Médicale* for March 1831, and subsequently transferred in substance to the *Lancet*, April 1831; and *Johnson's Med. Chir. Rev.*, October 1831. It, however, escaped the vigilance and industry of both Dr. C. Johnson and Dr. Copland, and is dismissed with a slight allusion by Dr. Roe, because chemical demonstration was wanting.

Dr. Bland considers the primary cause of the disease to consist in an irritation, not an inflammation, of the mucous membrane of the bronchi, under which the glands and follicles of that membrane pour forth a specific secretion saturated with hydro chlorate of soda, the irritation of which, when it reaches the upper part of the trachea and larynx, throws the muscles of the glottis and of respiration into spasmodic action for its expulsion, in a manner exactly similar to any foreign body which accidentally enters the larynx.

From this theory of the nature and seat of the disease I so far differ as to regard the primary affection of the bronchial membrane as inflammatory in its nature, and believe that it will be found on careful observation to be attended by more or less fever of an analogous character to that which attends contagious catarrh or influenza; but to that part which views the pre-

sence of a saline secretion in the trachea as the proximate cause of the convulsive cough which ushers in the second stage, I give my unqualified assent: because I believe it demonstrably true. When, however, the convulsive hooping is fully established, it very commonly happens that symptoms which mark the third, or what may be appropriately termed the complicated stage are developed, and continue to mark the varying and formidable phases of the disease which mostly attract attention in practice. These tertiary phenomena usually manifest themselves—1st, as special lesions of the nervous and muscular systems; 2dly, as special lesions of the respiratory organs; or 3dly, as the more general affections of fever and cachexia, and are present in individual cases in every conceivable variety of combination.

The 1st class comprise—an exalted sensibility, and morbidly susceptible state, of the membrane of the larynx, the pharynx, the epiglottis, under which death from asphyxia may suddenly occur—morbid association of the action of the muscles of glottis and respiration, in consequence of which the cough continues from mere habit, or is reproduced by the most trivial irritation of the air passages; reflex irritation, often passing into inflammation of the nervous centres of the pneumogastric nerves, involving those of the phrenic nerves also; and finally, these reflex affections may extend to the whole of the brain, or to the medulla oblongata and their meninges, and prove fatal by inducing general convulsions or hydrocephalus. All these, be it observed, are pathological conditions of the nervous system which have been so constantly put forward in high relief by the advocates of the nervous theory as proximate causes of the disease itself.

The 2d class of tertiary phenomena include the various congestive and inflammatory affections that result from the mechanical disturbance of respiration and circulation, and the extension of the primary bronchial inflammation to the trachea, larynx, and pharynx, and the tissues of the lungs themselves. Epistaxis, hæmoptysis, and fatal emphysema from extensive rupture of the air-cells, have occurred within my own experience, and have apparently resulted from the mechanical violence of

the cough acting upon tissues previously weakened by disease.

Of the 3d class I have only to observe, that in the absence of cerebral or pulmonary inflammation, the fever of the third stages is always asthenic, and often assumes a remittent type when the cachexia is of a marasmic character.

The evidences of the truth of this theory, upon which I place reliance, are—the testimony of adults, who have been attacked by the disease, to the unusual and excessively saline taste of the expectoration so long as the paroxysms are severe—the resemblance of the expiratory efforts in hooping-cough to those made by the excitomotor system, for the expulsion of a foreign body from the larynx; the very adequate explanation it affords, both of the extraordinary and spasmodic muscular actions which accompany the cough, and of its occurrence in paroxysms after intervals of uncertain duration; and lastly, the key which it furnishes to the chaotic host of apparently opposite remedies that have obtained professional or popular reputation in its treatment.

Of these remedies, we find one group adapted to lessen the original bronchial affection, and favour the expulsion of the offending mucus—as emetics, antimonials, and counter-irritants applied over the chest; another, which acts by altering the quality of the secretion, as the alkaline carbonates, ammonia, and the sulphuret of potass, so strongly recommended by Dr. Bland himself; another, by exciting a new action in the bronchial membrane; and constricting the vessels put a stop to the secretion in a manner perfectly familiar to the physician in chronic bronchitis, and to the surgeon in purulent ophthalmia—the superacetate of lead, alum, common resin, T. cantarides in Bals. Copaiba, tar vapour, and even the inhalation of nitrous vapour, &c. Others, again, as musk, both native and artificial, camphor, arsenic, conium, belladonna, opium, and hydrocyanic acid, are more especially adapted for the nervous lesions; and antiphlogistic measures meet the inflammatory lesions of the third or complicated stage.

The popular remedies are, indeed, so numerous, that one is strongly reminded of the custom which Mr. Pettigrew informs us, in his late interesting

work "On the Superstitions connected with the History and Practice of Medicine and Surgery," p. 73, is common in Devonshire and Cornwall, and some other parts of England, viz. "to inquire of any one riding on a piebald horse of a remedy for the hooping-cough, and whatever may be named is regarded as an infallible specific."

There is yet wanting to complete the whole a chemical examination of the bronchial secretion, to determine the exact nature of its saline constituents. From this, as I have not had the disease, prudence will lead me to refrain; but I shall conclude by expressing the hope that ere long it will be instituted by the advanced chemical pupils of this hospital, under the auspices of the pre-eminently qualified author of the article "Mucus," in the *Cyclopædia of Anatomy and Physiology*: the scientific physician who so worthily fills the chair of the Society on the present occasion.

ANALYSES AND NOTICES OF BOOKS.

"L'auteur se tue à allonger ce que le lecteur se tue à abrégé."—D'ALEMBERT.

Graefenberg; or a True Report of the Water Cure: with an Account of its Antiquity By HENRY HAY GRAHAM, M.D. London, 1844.

"THE combat thickens!" The desire to obtain possession of the ear of credulous John Bull, with a view to get hold of his person, and wring out of his purse some of his superfluous gold, prompts those who study his varying humours to present him with numerous treatises on each of his successive hobbies every winter, pretending to be the sole proprietor of the "arcaneum magnum." For our own parts, we decidedly like this system, and are much edified when "partners" fall out, and each publishes his separate manifesto, representing his former "partner in distress" as an arch impostor. In this way we get some of the "secrets of the prison-house." In one point they all agree, viz. in speaking disrespectfully of Priessnitz, and indulging in every kind of insinuation against him and his establishment; not with the humane intention of warning their fellow creatures against the risk of falling victims to their credulity, but with the sordid

hope of diverting some of the golden funds of his Pactolus into their own muddy streams. True to this aim, there runs through the "*true* report of Graefenberg," a current of innuendoes, hints, some slight, some broad, but all most skilfully introduced, and the whole admirably calculated to impress John Bull with the belief that he will do well to stay at home, and be doused by native *aquarii*. Hence, we are told the process is of British origin (p. 48), and Priessnitz is openly accused of borrowing his plan from Dr. Hulm, (see Appendix to the True Report, p. 155), who borrowed his notions from the work of Sir John Floyer and Dr. Baynard; *argal*, British practitioners should know best how to employ it. And who can wonder that *disinterested* writers should strive to keep John at home, when told that Priessnitz, who is at times called the "inspired peasant"; at others "the philosopher," (p. 122) while at others he is designated by no gentle terms, has accumulated what our contemporary, the British and Foreign Medical Review, calls "solid pudding" to the amount of £50,000, or as Dr. Graham affirms, £100,000 (p. 44.) Thus we have the following: "Those who are desirous of experiencing it will do well to seek out some establishment near at home, rather than undertake a long journey, and submit to all the privations and inconveniences of Graefenberg" (p. 36.) This shows a nice acquaintance with John Bull's weak points; he loves *comfort*, and does not like to submit to privations, especially in his accustomed good cheer. Following up this ingenious plan of giving John praise, we have, at page 42, a most enchanting picture of the company, menage, and diet, at Graefenberg. "*The food at Graefenberg* [these italics are in the original, and well do they intimate how the statement is expected to tell on John's gustatory nerves] is abundant, but of the worst and coarsest quality, such as would be scarcely tolerated in our workhouses. Sour ryebread with caraway-seeds; cow-beef, with scarcely a particle of fat." Read this, John! and stay at home.

Least this should not be sufficient to dissuade John from attempting the "dangers of the sea," it is followed by a statement that scarcely *one* case out of *twenty* is cured. Still "hope springs

eternal" in the sick man's breast; and each one calculates on being the fortunate twentieth, who is to be the object of envy to the nineteen uncured. Therefore, twenty will go. This must not be, so we are next told that three or four years are required for the cure, (pp. 22 and 40). "Four summers, with the length of four long winters" at Graefenberg! But he adds, significantly, "a very few try a second winter," (p. 41). Nor is the company of the choicest description. "Two-thirds of his patients are said to be syphilitic," (p. 59), chiefly young men, who surround new comers, and recount to them the "miracles" that Priessnitz had performed—"for a consideration." "These gentlemen [*italics in the original*] were much in debt for board and lodging, and were clearing off their score by a system of 'puffing,'" (pp. 11 and 141). All this may be insufficient to deter resolute John Bull; there is another hope of doing this by working on his "better half's" feelings of modesty. In a fatal case of an English young lady, who went thither in perfect health, Miss S. S., and who fell a victim to her folly, Priessnitz excused himself from being answerable for her death, by saying: "It was his practice to judge of the inside by the skin, (his most appropriate motto might be, *Te nori intus, et inente*), but that he was restricted in his observations in her case, and therefore could not tell what was going on within-side." He then mimicked the tone of her voice, and her retiring modesty, when he once attempted to remove her bathing dress. He afterwards ridiculed the English ladies for using bathing-dresses at all, so different from the custom of his own countrywomen. And all this was said and done with a sort of acting or imitating their manners, highly amusing to his hearers, who burst out with repeated shouts of laughter." Natural enough on the part of an audience two-thirds of which wore the "corona veneris." Well may Dr. Graham add, "Such is the great, the immortal Priessnitz! Proh pudor!" (p. 55.)

Should all this fail, there remains the decisive "corps de reserve;" the fatal and nearly fatal cases: of the former, the case of Miss S. S. is made a great deal of, being well harped upon throughout the book, and of the latter, the case of Dr. Graham himself, who

adventurously essayed "the water-treatment" for the gout, and having "escaped with the skin of his teeth," narrates his case for the warning of his country men, like those who escaped shipwreck, who suspended their dripping garments in the temple of Neptune,

Indicat invida
Suspendisse potenti
Vestimenta maris Deo,

i. e. the demi-god Priessnitz, (p. 141.)

A careful perusal of the whole of Dr. Graham's book leaves on our minds the impression that, like a young barrister, eager to gain his end, he cites witnesses who prove "too much," convincing us not only of the danger of putting ourselves into the hands of the "illiterate peasant of Graefenberg," but of the danger of the treatment called "hydropathic," in nearly all cases. This was not the object aimed at, as may be gathered from the conclusion: "In the hands of Priessnitz and his followers, it has become a quack medicine—an universal nostrum—and, like every other remedy indiscriminately used, is frequently as productive of injury as of benefit. Used in moderation, and judiciously combined with other remedies, there can be little doubt but the greatest advantage would be derived, especially when united with the occupation and amusement of a large establishment," such as that of ———: our readers can fill up this hiatus.

Note.—We are indebted to Dr. Graham for the confirmation of a suspicion which we entertained and expressed when reviewing (see MEDICAL GAZETTE, last vol. p. 198) the "Hand-Book of Hydropathy" of a self-styled Dr. Weiss. Our point of interrogation after his title of Dr. (?) was quite appropriate. Dr. Graham can bear no rival near the purse of John Bull, and says "such are the men who generally pretend to consummate skill in the use of this their infallible remedy, and who, with the veterinary Weiss, the nephew of Priessnitz, (one of the common bath attendants at Graefenberg), and a host of other Germans, inundate this country, and not unfrequently assume the titles of surgeons and graduated physicians," (p. 14.)

Since we are on the subject of German humbugs, we may remark that more than one writer on hydropathy has addressed Liebig as favourable to that plan. We give them, therefore,

the advantage of his indignant disclaimer.

"The existence of hydropathic institutions—those dens of covetous and rapacious gamblers—where the wretched invalid resorts to throw the dice for health and life; the rise and progress of the homœopathic system, which treats truth with scorn, and bids defiance to common sense, loudly proclaim the need which exists for the adoption of settled principles, definite methods of research, and a systematic arrangement, to guarantee their attainment and retention (in the practice of medicine)."
—Liebig, in *Lancet*, of 29th of June, 1844. Also, in *MEDICAL GAZETTE*, of 5th July, 1844.

The homœopaths court more blows: not content with Dr. Wood's exposure, they have dared him (but from behind the ambush of a careful *incognito*), in sundry pamphlets, displaying

"sounds without sense,

And all the florid glare of impotence,"

to administer a little more chastisement to them, in the form of a *Sequel to Homœopathy Unmasked*, which is well worthy the perusal of our readers. But it is scarcely worth while fanning the dying embers of homœopathy.

MEDICAL GAZETTE.

Friday, November 8, 1844.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

THE RESOLUTIONS OF THE ROYAL COLLEGE OF PHYSICIANS, AND REPORT OF THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH, ON THE MEDICAL BILL.

WE are sometimes rather at a loss for a text to dilate upon in these our weekly lucubrations. In ordinary times it is not even once a week, and at the exact interval from Thursday afternoon, that aught of peculiar interest in the ethics or politics of the medical profession regularly occurs; and to sit down with the purpose of writing an abstract essay upon even the most important topic

never answers the end. The subject must not be abstract, but practical; not of yesterday, but of to-day; not of the "Pyrenean and the river Po," when the reader anticipates the Home Office, Pall-Mall East, Lincoln's Inn Fields, and Bridge Street, Blackfriars, as the theme. We are sometimes at a loss for a text, we say; in these stirring times we have a dozen starting up before us, each more urgent than the other for notice. Some of the most interesting we are almost fearful of meddling with, however: we would not willingly give umbrage to any individual among the many distinguished men who have been our hitherto friends and supporters; but intimately convinced that these our esteemed friends are wrong,—they will pardon us for being so bold,—and feeling ourself with one of "the prime feathers in the wing that moves the world," as our eloquent friend Dr. Marx has it, in our hand, with the very tablets before us, too, upon which the laws that rule the world are written, how can we but in all honour and truthfulness do our best to leave traces there of what we feel mentally persuaded to be the right and the true, and worthy as such of influencing the code that is to govern the class in society of which God and our own free choice hath made us a humble member? We appeal to our motto as giving us a claim to perfect freedom in the discussion of the questions that agitate the medical profession at this really momentous crisis: "Licet omnibus," &c. "Be it allowed to all, be it allowed also to me, to uphold the honour of the medical profession; with power to come before the public, I decline not the *danger* of speaking my thoughts."

The RESOLUTIONS of the Royal College of Physicians, and the REPORT of the Royal College of Surgeons of Edinburgh*, are probably the documents of

* Vide last week's Gazette.

highest weight that lie before us, and that therefore crave earliest attention.

Both of the Northern Royal Colleges are even urgent in their approbation of the measure as produced by Sir James Graham. But they take "The Bill" apart from what we cannot but regard as its inseparable appendix, the New Charter of the Royal College of Surgeons, and thereby make nugatory much, or almost all, that can be said in its favour. Our brethren north of the Tweed can form no estimate of the way in which the profession south of that stream are likely to be affected, are already affected, by it. The distinction into two classes of members in the College of Physicians, proved the cause of bickerings and heartburnings for something like a century or more; and the unhappy idea of introducing the same apple of discord into the College of Surgeons has taken possession of the minds of the instigators of Sir James Graham's Medical Bill. Nineteenth, nineteen-twentieths of all that is most confided in and respected in the medical profession of England, is at this moment cut off from its connection with any legitimate or possible head, or, we ought rather to say, place of shelter for its head; for the brains are in, and active enough; and though it were the head from which the body of the profession was actually severed, we do not remember, when we saw a man guillotined in the Place de Grève in the days of our youth, that the head did much better without the body than the body did without the head;—it was a woful disjunction to both.

Returning to the Resolutions of the Edinburgh Colleges of Physicians and Surgeons;—the Physicians testify their satisfaction that the bill for the better regulation of medical education and practice, so long expected, has at length been laid before the House of Commons; the Surgeons "observe with the

greatest satisfaction that the grievous impediments to the practice of the healing art, arising from the faulty state of the laws affecting the medical profession, of which the College have so long unavailingly complained, have engaged the attention of Her Majesty's advisers; and that a legislative remedy, proposed by them, has been read a first time in Parliament."

The satisfaction of the Physicians is simple: the College of Physicians of Edinburgh, if not a rich, are still a solvent body, and they are not so loud in their approbation as their brothers the Surgeons; they have gone the even tenor of their way, never climbing great heights, and therefore running no risk of suffering great falls. The Surgeons of the North, like the Surgeons of the South, are on the whole a more dashing and ambitious set of men than the Doctors; they come more before the public; their operations dazzle the eye and the imagination; the operation of the physician's dose of jalap goes all the world knows where, and has nothing brilliant about it. With an unusually prosperous state of affairs some years after the late war, the Edinburgh College of Surgeons became ashamed of their dingy domain in Surgeons' Square, and built themselves a magnificent temple fronting one of the principal thoroughfares of the city; they took up a still more conspicuous position than they had yet held. But stone and lime, or bricks and mortar as we say in the south, are costly articles; the College contracted a large debt for its new building, and the necessity of obeying the behests of the Apothecaries' Act of 1815 being more forcibly borne in upon the minds of students, and other circumstances concurring, the number of students at Edinburgh began to fall off; the examinations at Surgeons' Hall fell off in a still greater measure, and at the present time the

College is literally bankrupt, and have actually, we believe, had a proposal made to them by one of their leading members to sell their museum in order to find ways and means to meet current expenses. The "grievous impediments to the practice of the healing art," of which they speak, being interpreted, means nothing more than this; that the Apothecaries' Company kept the sword of the law suspended over the heads of all the men settled in England who held the diploma of the Royal College of Surgeons of Edinburgh. Nay, we rather think it let the weapon fall upon more than one occasion. The abrogation of the Apothecaries' Act is what the Royal College of Surgeons of Edinburgh are bent on. With uniformity of privileges, the diploma obtained in Edinburgh, giving authority to practise in Liverpool and Manchester, in Carlisle and Truro, the Edinburgh College naturally expect that they will be able to recruit their exhausted exchequer, and perhaps find themselves in a position to keep the roof in Nicholson Street over their heads, and even to retain the museum which cost them so much money. We have already explained several portions of "the Bill," and its appendix, the London College Charter; we are happy to supply our readers with an explanation of the diversity of tone assumed by the two Royal Colleges situated in the capital of the north.

The College of Physicians and College of Surgeons alike felicitate themselves in the knowledge that the two grand principles for which they have both long contended, viz. uniformity of education and qualification, are those that form the grand principles of the legislative measure. We have shown most clearly that there is no provision for any thing of the kind in the bill. The licentiate in medicine and surgery is admissible at 21; the Universities

will create bachelors of medicine at 22, upon which they may register as authorized practitioners, preparatory to going to a College of Surgeons or a College of Physicians, according to their bent, at the respective ages of 25 and 26. And how can uniformity of education and qualification be vindicated for a measure that leaves the profession open to every chemist and druggist's boy who has neither education or qualification?

The principles above specified—which we have shewn to be in nubibus, or in the imaginations of the authors of the Resolutions—carried fully into effect, the Physicians go on to say, would confer a great benefit on the profession and the public, &c. The profession, from the extreme north to the farthest south, from the utmost east to the remotest west of this division of the empire, have emphatically declared that they do not think it will; and how the public are to be better served than they are, when the profession shall be open for every cow-leech and farrier, every collector of simples and compounder of drugs, to practise upon their weakness and their ignorance, we own we do not understand.

The College of Physicians of Edinburgh proceed, and think "that in providing the public with a supply of fully qualified practitioners, government do all that can be attempted by legislative enactment:" government leave the ignorant public, we again say, to the mercy of chemists and druggists, who have no knowledge of physiology or pathology, or practice of medicine. The Edinburgh College know nothing of the state of ignorance in which the vulgar of this division of the empire are plunged in regard to medicine. The chemist's and druggist's shop is universally the "Doctor's shop," and nine in ten of all the labouring community do not

know that the man behind the counter who orders medicines for the ailments of themselves or their children, when he is dishonest enough to do so, which he is nineteen times in twenty, is as ignorant as they are themselves, in regard to the nature of the disease for which he is prescribing, and the fitness of the remedy which he has the boldness to administer. They have now few or no chemists and druggists in Scotland, of the class and stamp of those we have in England; the profession there is on a totally different footing from what it is in this country.

The College of Surgeons highly approve of the registration, as giving the public the advantage of knowing what practitioners are qualified. The vast mass of the public will never appeal to the registration for any information of the kind; they will still apply to the "Doctor's shop" that is nearest them—to the "healer," as they will believe him to be, who stands behind the counter, and has the gas-lit window with the red and blue bottles, without a notion of the risk they run of being helped out of their life instead of out of their disease, as they intended. If government persists in giving the disgracefully ignorant community of England, the Bill for the Better (*Qu. the worse*) Regulation of Medical Education and Practice, let it begin by teaching them letters, that they may be able to refer to the register, lest they get poisoned through inability to do so. The spiritual and immortal part has been that for the improvement of which elementary education has hitherto been most urgently pressed and willingly granted; the corporeal and mortal being about to be brought into jeopardy in addition, by the new Medical Bill, ought surely to be urged as a motive the more for educating the people.

But we have transgressed our wonted limits, to the exclusion of more valua-

ble matter; the position of the authors of the Resolutions and Report, however, made it imperative on us to go at least thus far this time, into a review of their conclusions. We presume we must have a very considerable strand of what Burns called "the stalk of earl-hemp in man" in our constitution: we are not one of those whom Cataline charged with being "*in servitutem parati*," fit for slavery; and we cannot conceive Royal Colleges of Physicians and Surgeons, and by implication and of necessity the Medical Faculties of the Universities of the land,—those aggregates surely of all that is most intellectual, most learned, most fitted to exercise self-government, one would imagine,—turned into *sub-committees*, without the power to control their own acts or to make their will prevail, supervised by others, having a supreme council set over them to review their measures, the judges of their conduct being a Secretary of State and a majority of non-professional persons, like himself utterly and necessarily ignorant of every thing appertaining to medical science and practice,—*περί πάντα την Ἐλευθερίαν*, is our motto.

We beg to call attention to the following letter, which we have just received:—

To the Editor of the Medical Gazette.

SIR,

WILL you have the kindness to inform me what is to become of myself, and other members of the College who, like myself, have been many years in practice as pure surgeons, and have no inclination to go up again for examination, although tempted by the high distinction of ranking very nearly, though not quite, equal to gentlemen twenty years younger than ourselves, for the small sum of thirty guineas? It is clear from the wording of the clauses that we can have no place in the Register under Sir James Graham's Bill. Are we, then, to put our diplomas in our pockets, and turn quacks;

or must we take to the wine and coal business?—I am, sir,

Your obedient servant,
Q.

November 5, 1844.

We should gladly give our correspondent the information he requires, but regret extremely that we cannot. We trust, however, that he, along with every other worthy member of the Royal College of Surgeons, will obtain it directly and ere long from the Council of that Corporation, and that it will be such as will prove satisfactory to all.

Our sense of justice has been appealed to by Dr. Chambers, of Colchester, in connection with the strictures we made on the discordant tenor of the observations that were made by the speakers, and the purport of the resolutions that were passed at the meeting held in that town.

Dr. C. informs us that he was overruled in the preparation of the resolutions, which were not such as he approved of, and that he and several of his friends did not speak pointedly against them, only that the harmony of the meeting might not be disturbed. We meant nothing either personal or disrespectful to Dr. C. in our remarks, and here publicly express our regret that a single word we said should have caused him annoyance. Want of space alone prevents us from publishing his letter.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN IN LONDON AND ITS VICINITY.

A HALF-YEARLY General Court of the Members of this Society was held last Wednesday evening, at the Gray's Inn Coffee House, Holborn, and was very numerous attended: Dr. Mann Burrows, V. P., in the chair.

After the Minutes of the last General Court, and of the subsequent Court of Directors, had been read, a ballot took place for the election of officers. Sir Charles Mansfield Clarke, Bart., the senior Vice-President, was unanimously elected President, in the

room of the late Sir Henry Hallford. Dr. Latham was elected Vice President, in the place of Sir Charles Clarke, and Mr. Hunter, of Mining Lane, Acting Treasurer, in the room of Mr. Bacot, who resigned. In place of the six senior Directors, who retired in rotation, the following gentlemen were chosen as Directors:—Drs. S. W. Merriman and Alex. Sutherland; Messrs. Bacot, Walne, Miles, and Headland.

Much regret was expressed at the Widows and Orphans lately relieved having received smaller annual grants than those previously on the list, but it was shewn, that after giving the subject the very fullest consideration, the Court of Directors did not feel warranted, by the state of the funds, in making larger grants at present; for, although the capital continues to increase every year, the number of applicants increases still more rapidly.

The capital, invested with the Commissioners for the Reduction of the National Debt, amounts to £42,000, and yields an income of £1550. 33 widows, and 23 children, now receive relief; the former £35 or £30, and the latter £12 or £8 per annum. It is earnestly to be desired that this Society may receive from the heads of the profession such universal support, that it may continue to confer on the widows and orphans of the less affluent, those valuable benefits, which, for fifty years, it has so efficiently afforded.

PHYSICAL SOCIETY OF GUY'S HOSPITAL.

D. G. O. REES, Esq., in the Chair.

Nov. 2nd, 1844.

THIS Society was occupied in hearing and discussing the views on the nature and seat of whooping cough, originally propounded by M. Bland, and maintained by Mr. Streeter, in the paper which appears in an earlier part of our current number. These views were opposed by Dr. Golding Bird, Dr. Gull, Dr. Munk, and Dr. Barlow, and supported by Mr. Blenkarn, and the author of the paper. In the absence of chemical demonstration, Dr. Bird held that no reliance could be placed on the fallacious test of taste brought forward to prove the existence of a saline secretion, and supported the theory of Desruelles, which views the disease as at first inflammatory, and afterwards spasmodic, by a reference to its pathology and symptoms. He contended that alkalies are serviceable, by rendering the mucus more soluble and easy of expectoration, and not by changing its irritating quality. Dr. Munk and Dr. Barlow believed the true proximate cause of the disease to be a contagious miasm; the former

considered it a true blood disease, and the paroxysm as essentially referrible to spasm. Mr. Blenkarne thought the views advanced worthy of great consideration, as they afforded something like intelligible grounds for the employment of remedies. Questions were also put by Mr. Hilton and Dr. Hughes in reference to pathological details, and the supposed gastric origin of the disease. Mr. Gaitskell strongly recommended prussic acid as a remedy. Mr. Streeter in reply conceded that in strict language miasm must be regarded as the proximate cause of the bronchial affection, but defended the accuracy of the views he had introduced to the society. He believed the evidence of taste was perfectly adequate to establish the existence of an excess of saline matter in the mucus, and that this was the true exciting cause of the paroxysms, and of that morbidly susceptible state of the membrane of the larynx, which, by reflex irritation conveyed to the nervous centres, produced the nervous lesions to which most writers had attributed the spasmodic stage. He also explained the gastric disturbance alluded to by Dr. Hughes, by the same cause, and added some pathological details. The customary thanks of the society were voted to the author, and a paper "On the Depuration of the Blood, by Dr. Barlow," announced from the chair, for that day fortnight.

title of *candidatus medicinæ*; to this examination also belongs what is called the *disputatio pro exercitio*, a Latin thesis, generally upon a chemical subject, being sustained, the candidate having his professor as respondent.

Upon these elementary medical studies, follow the practical courses, comprising ten months' attendance upon the hospital, and two months' attendance upon the lying-in institution, in which the candidate is either accommodated as a lodger within the hospital, or shews himself daily at the visit. He is in this period of his study required to look after the sick, to keep the books of the cases, to do minor surgical offices, and to watch by patients who are more seriously ill. At the end of this year he is examined as *medicinæ licentiatas*, being taken upon therapeutics, practical surgery, including midwifery and medical jurisprudence (subjects in the study of which he has lately been particularly engaged), after which he receives his license to practise. He now maintains his *disputatio doctoris*, and is advanced to the degree of doctor in medicine without further examination.

The school at Stockholm does not grant degrees in medicine, having no authority so to do. The creation of doctors in medicine always takes place in batches of twenty or thirty, and is made the occasion of a great festival.

To acquire a title to higher offices, to be employed by the state in any public situation, the doctor or physician must further be a *magister chirurgiæ*, to obtain which rank he must undergo a special examination before the professors of the Stockholm school of medicine, the *Institutum Carolinum seu Medico-Chirurgicum* of Charles XIII., instituted in the year 1810, and originally destined as a school for army surgeons during the war; but the necessity for it in this direction having ceased, it has been advantageously continued in the manner just stated. According to the catalogue of lectures for the year 1840-41, this school reckons eight professors, and several associates; the professors reading courses of lectures from the beginning of October to the end of May, upon operative surgery, surgical instruments, and bandages (Eckströmer); practical medicine; midwifery and the diseases of pregnancy, of nursing women and of infants at the breast; on surgical pathology, therapeutics, and practice (clinical surgery); on zoology; human anatomy (Professor Retzius), comprising instructions in medico-legal examinations and inquiries; on medical botany, medical zoology, and materia medica; on animal chemistry, inorganic chemistry, and chemistry; a special clinical course on the diagnosis and treatment of the diseases of the chest,

COURSE OF MEDICAL STUDY IN SWEDEN.

Young men who intend to devote themselves to the profession of medicine, after their preliminary general and classical education is completed, are required to proceed to one of the Swedish universities, Upsal or Lund, where they are not allowed to matriculate until they have gone through a preliminary or *student's examination* before a special committee. They then enter upon a course of philosophical study, and undergo another examination, usually after the lapse of from two to three years, the *medico-philosophical examination*, which embraces the Latin and Greek languages, mathematics, history, logic, ethics, legal philosophy, political economy, natural philosophy, chemistry, and botany. It is only now, and after having acquired the title of *candidatus medico-philosophicus*, that the student begins his medical studies, properly so called, and which he may pursue either at Upsal or Lund, or at the medical school of Stockholm. The medical studies consist in anatomy, physiology, medical botany, zoology, materia medica and pharmacy, pathology, and the principles of surgery; upon which subjects, after the lapse of two years more, another examination is instituted, which, successfully stood, the student acquires the

with particular reference to the methods of investigation by auscultation and percussion. The students meantime have daily access to the Royal Hospital, called the Seraphim Lazaretto, the Royal Garrison Hospital, the General Lying-in Hospital, and the Foundling Hospital; but in each instance only during the visit of the medical officers or of the apothecary. They have, further, access to the museum daily, and twice a week to the library for the purpose of obtaining books. It is very important to observe, that the pupils of the Charles's Institute are also admitted to the great Military Hospital, where there are beds for a thousand patients; an arrangement which harmonises with the practice of selecting military medical officers from among the civil medical practitioners, the selection taking place after examination, and the number of applicants always securing as many as are required of the best informed.—*DR. KRIEGER, Medicinische Zeitung, No. 11, 1844.*

DEATH FROM INTERNAL HEMORRHAGE AFTER A VIOLENT EFFORT.

A. A., 26 years of age, of great muscular strength, laid a wager that he would perform a certain piece of work with the shovel or dung-fork, in the farm-yard, in the course of two hours. He had almost completed the work, and won the wager, when he began to complain of pains in the bowels. He drank several glasses of brandy, and went on with his labour; but the pain in the abdomen increased, he was seized with a violent shivering fit, and had to be carried to bed, where he fainted. The patient was ordered a dose of castor oil, and an oily emulsion. In the evening the patient still complained of a feeling of chilliness, of pains in the belly, and a disposition to vomit. The belly was very much distended, and painful on pressure; the pulse was extremely small and contracted; the countenance was sunken, with the expression of deep suffering. The patient was bled, but syncope supervening, the vein had to be stopped. Twelve leeches were ordered to the belly, and repeated clysters prescribed, the patient not having yet had any opening from the bowels. These means having remained without effect, the patient was put next morning into a warm bath, and felt himself relieved, but the distension of the belly went on increasing. The patient now became excessively anxious; he had long fits of shivering, cold extremities, clammy sweats, hicough, and facies Hippocratica. In the afternoon, having requested to have another warm bath, he was put into it, but within five minutes he was taken out dead.

The body was extremely pale; the abdomen distended to the bursting. As soon as the abdominal parietes were cut through, an interminable stream, as it appeared, of fluid blood flowed from the opening, so that the room immediately became inundated with it. All the blood having at length drained off, the viscera, liver, spleen, bowels, &c. presented themselves without a trace of inflammation. After a long search, I at length discovered a rent, several lines in length, in the splenic vein, from which the fatal hæmorrhage into the abdomen had taken place.—*DR. MILING, Medicinische Zeitung, No. 8, 1844.*

LEAD COLIC.

DR. HOFFMANN, of New Ruppın, states that the combination of alum and opium cannot be sufficiently prized in lead colic. Inflammatory symptoms removed, it soothes the pain, keeps the bowels regular, and tranquillizes the patient.—*Ibid.*

URINARY CALCULI OF REPTILES—FOSSIL UROLITES.

M. DUVERNOY lately laid before the Royal Academy of Sciences an account of the urinary calculi which *M. Lesueur* had discovered in two specimens of the tortoise—*Trionix spiniferus*, and which consisted of a mixture of phosphate of lime, carbonate of lime, and organic matters. One of the calculi was of large size, and weighed upwards of 260 grains, and was composed principally of phosphate and carbonate of lime, grains of sand, and organic matter. One of the calculi appeared to have been formed upon a fragment of a shell as a nucleus; and the other and larger one, as has just been seen from the statement of its composition, contained a mixture of grains of quartz. The water in which this *Trionix* lives must therefore find access to the cloaca or urinary bladder of the animal. *M. Duvernoy* further shewed, that many of the bodies called coprolites were in fact the solidified urine of reptiles, and that they had been confounded with the masses of intestinal excrementitious matter which constitute true Bucklandian coprolites. The urine in the Saurii, in the Ophidians, and the Crocodiles, at the moment of its excretion appears to consist of a soft and ductile paste, which is moulded into a particular shape as it passes the cloaca; exposed to the air it soon acquires a stony hardness, which enables it to resist change. A number of these *urolites*, mixed among proper coprolites, discovered by *M. Robert*, are found in fact to contain phosphate and urate of lime, and to have a general composition very analogous to the solid urine of the lizards and serpents of the

present day. This circumstance, coupled with their form, enables M. Duvernoy to say, that those fossil uroliths which have not a spiral form have proceeded from crocodiles, whilst those having a decidedly spiral form have been passed either by lizards—Saurians, properly so called—or by serpents—Ophidians.—*Comptes Rendus*, vol. xix. No. 5.

CURIOUS CASE OF PARALYSIS.

A MAN, 70 years of age, gouty and lame through gout of the left foot, after drinking a few glasses of beer, was struck apoplectic, with hemiplegia of the left side, showing signs of congestion to the head, and vomiting a clear watery fluid. The left or paralysed arm was completely abstracted from the influence of the patient's will, save that he had the power left of grasping my hand strongly when I put it within his hand; he could not, however, give me his hand when desired to do so, or in any way to guide it as he wished; the hand seemed to be jerked involuntarily towards the man's face, so that he struck himself continually when he attempted to move the arm. The patient, by blood-letting from the opposite arm, leeches to the head, blisters to the spine, &c. recovered in great measure; though from his great age it is doubtful whether or not he will recover completely.

This case is interesting, inasmuch as neither sensation nor motion is completely destroyed. The patient has feeling in the arm when it is touched, and can grasp a hand forcibly; he can also move the arm, and that actively, but he cannot control its movements; and curiously enough, the involuntary tendency is towards his own face. I do not remember to have met with a case precisely of the same kind in the course of my reading; nor do I feel myself competent satisfactorily to explain the phenomena.—*Dr. Lion, in Casper's Wochenschrift*, No. 33.

CASE OF CONGENITAL DEFICIENCY OF THE STERNUM.

A MAN, strong and well-built, 5 ft. 3 in. German (about 5 ft. 4 in. English) in height, and 22 years of age, was found, on examination for military service, with a remarkable deficiency of the sternum. In the middle of the chest the motions of the heart could be perceived at a considerable distance. The sternum was entirely wanting, with the exception of a small rudiment in the situation of the ensiform cartilage, so that the heart was only covered in the middle line of the thorax by the common integuments. On applying the hand, the alternate contractions of the auricles and ventricles could be distinctly perceived. The extre-

mities of the ribs on either side, where they ought to have been in contact with the sternum, were found connected in a continuous, apparently cartilaginous line. The young man declared that he had always enjoyed good health, and that he had never suffered from the deficiency pointed out in his business of musician.—*Medicinische Zeitung*, No. 10, 1844.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Gentlemen admitted Members on Friday, Nov. 1.—R. F. Freeborn.—F. J. Brown.—J. Millard.—H. H. Snell.—S. M. Macswiney.—G. Ashdown.—B. L. Jemmett.—F. Brittan.—G. Keane.—R. Fletcher.

APOTHECARIES' HALL.

Gentlemen who have obtained Certificates, Oct. 31.—F. J. Brown, Standgate Creek, Rochester.—W. Finer, 6, North Place, Kingsland Road.—J. Williamson, Longloathley, Penrith, Cumberland.—R. Ellis, Brompton.—J. H. Gale.—W. Stevens.—C. L. Wall, Worcester.—G. Rodwell, Choseley Dorking, Norfolk.

NEW CONTINENTAL WORKS.

Adelmann, G. F. B., Untersuchungen über Krankhafte Zustände der Oberkieferhöhle. 4to. sewed. Dorpat.—(On Diseases of the Antrum.)

Archiv für physiologische und pathologische Chemie und Mikroskopie in ihrer Anwendung auf practische Medicin, hrsgb. von F. H. Heller. 1st Band in 3 Hefen. 8vo. sewed. Berlin.—(A continuation of the Work begun by Simon.)

THE LONDON MEDICAL GAZETTE,

BEING A
WEEKLY JOURNAL

OF

Medicine and the Collateral Sciences.

FRIDAY, NOVEMBER 15, 1844.

INFLUENCE OF BURIAL CLUBS ON THE MORTALITY.

IN our number for August 23d, we published a short article "On the Influence of Burying Clubs in augmenting the Mortality." There we certainly dipped our pen into very deep-coloured ink, and having sketched a perfect murder of the innocents, our statement was treated as exaggerated, and but little heeded. There were some, nevertheless, who knew that the picture was not altogether overcharged. The excellent letter of Mr. Leigh, published in our number for Sept. 6th, came in confirmation of our "New View of English Society," and we now add an extract from the evidence of the Rev. Mr. Clay, forming part of the "Appendix to the First Report of the Commissioners of Inquiry into the Sanitary State of large Towns and Populous Districts," which we trust will satisfy all of the extent to which the practice we denounced was carried, and also incline men more to listen to the suggestion of the enlightened Secretary of the Poor Law Commission, on the necessity of having a properly qualified and responsible medical man appointed in each district or division of the country, to act as an Officer of Health, and to verify by inquiries at the time and on the spot the fact, and, as far as it might be ascertained, the cause of death; not to say any thing at present of the imperative necessity of the legislature interfering to make the practice of committing murder more difficult, by securing the ignorant public against the malpractice of ignorant chemists and druggists, who are the parties under cover of whom the present system of child-murder is especially carried on, when any show or pretence is made of having medical (!) assistance in the case.

Mr. Chadwick, in his supplement to the sanitary report, adverted to the cases of

murder discovered after interment, which a proper examination before inhumation might have prevented or detected. He also developed the existence of a practice of infanticide for the sake of "burial money" obtained from several clubs, in which the lives of the children were insured. Now, although the existence of the practice was proved by trials of cases in courts of law, the crime was by many deemed so monstrous, that its existence as a *practice* was believed to be impossible. It was, in particular, denied that any such practice had taken root in the town of Preston, which was distinguished by the number of its burial societies, although it was known that the payment of multiplied sums of burial money were insured from several clubs, on the death of the same child. The horrible reality has, however, been developed there also by a more recent investigation, by the Rev. Mr. Clay, a clergyman of that town, from whose interesting report on its sanitary condition the following evidence is extracted:—

Under the head of *Negligent treatment of children*, Mr. Clay says:—It is known that druggists are often resorted to for medicine and advice by the poor, and probably in some or many cases assistance from such quarters may have been obtained for sick children; but after making all allowances, it is to be feared that among certain classes of the poor a great amount of infant death takes place without any thing worthy the name of medical assistance having been obtained or even sought.

If the druggist is sometimes applied to for the medicine which, with greater propriety and safety would be prescribed by the medical man, he is too often asked for compounds which no medical man would prescribe; such as "Godfrey's Cordial," "Infants' Preservative," "Soothing Syrup," "Mothers' Blessing," &c. Returns have been obtained from all, or almost all, the chemists and druggists in Preston, of the quantity of these mixtures sold by each; and it is due to those

gentlemen to say, that the information requested from them was furnished in the most prompt and obliging manner. It does not appear that any one particular druggist sells the extraordinary quantity of Godfrey's Cordial, &c. which has been heard of in other towns, but that all vend the nostrums in question to a greater or less extent; and the aggregate of the whole quantity sold indicates that, allowing half an ounce per week to each family, upwards of 1600 families are in the habit of using Godfrey's Cordial, or some other equally injurious compound. It is not the least melancholy feature in the general aspect of these facts, that "Godfrey" (as it is familiarly called by its purchasers) is not given in ignorance of its noxious properties, a circumstance which the Charitable Society's agent had frequent occasion to notice. It is administered not so often, probably, by the mother, as by the nurse. The former, while working in the factory, intrusts her infant to an old woman or young girl, who may also have the charge of other infants; and this general nurse, in order to fulfil her task with as much ease to herself as possible, drugs the unfortunate babes with "Quietness." Mr. Robert Brown, surgeon, who collected much important information on this subject, had, among other communications made to him in writing, the following, which, although it may not at first appear very important, gives clear intimation of—the obtaining medicine and advice from druggists,—of mothers leaving their children in the care of most improper nurses,—and of the general suspicion of the use of deleterious drugs:—

"A child was brought to me for a little aperient medicine. The mother suspected that the person who nursed it had been in the habit of giving it some narcotic; it had not had more than two or three motions for the space of three weeks. I advised the mother to stay at home and attend to it herself. The advice was followed, and the child recovered in a few days."

Another highly respectable chemist and druggist writes,—

"A woman brought a bottle to me containing some medicine for examination, which was found to be an infusion of opium. She said a neighbour had given some of it to one of her children, upon the recommendation of some quack, who was in the habit of calling upon poor families for the purpose of selling the medicine. Her child became stupified in half an hour, and ultimately died. The man denied that the death was the effect of the medicine, as he had a very extensive sale, and could bring many proofs of the good resulting from its use."

Sick clubs.—Great pains have been taken by Mr. Holden to collect information relating to the management and statistics of the sick clubs in Preston. There is much reserve, however, in giving such information, and consequently less has been acquired than would have been desirable for the purpose of forming any general conclusions as to their operations and value. The following summary, circumscribed as it is, is sufficient to manifest the widely different amounts of sickness, and rates of payment, existing in only eleven clubs. The table relates to the year ending July 1, 1843.

BOROUGH OF PRESTON.

Report on its Sanatory Condition, by the Rev. J. Clay.

	Total Members.	Sick during Year.		Average Period of Sickness in Weeks.	Average Payment to each Sick Person.		
		Members.	Per Centage.		£.	s.	d.
Tee-Total	37	2	5.4	3.	1	10	0
Managers	47	5	10.6	8.2	4	2	0
Worthy	80	12	15.	7.5	3	7	8
Rehabites	116	19	16.3	3.7	1	17	7
Odd Fellows	689	124	18.	4.	2	0	0
Female Rehabites	30	6	20.	3.3	1	0	0
Forresters	230	52	22.6	8.8	2	11	0
Ebenezer	111	28	25.2	...	3	7	6
Catholic Beneficent	167	51	30.6	10.	2	19	3
Ditto, female.	80	25	31.2	9.	1	13	10
Perseverance	58	20	34.4	6.1	2	7	11
	1645	344	20.9				

There is one circumstance apparent in the above table, which adds further proof of the value of temperate habits among the poor.

The Tee-total Society (of which, however, the numbers are rather small for the purpose of any general deduction) presents not

merely the smallest proportion of sick, but a proportion amounting to little more than one-half of that next most favourable, while at the same time its members suffer the shortest average duration of illness. The extremes in the amount of sickness, as shewn by the proportion of sick members pressing in their respective societies, are very striking, being only 5·4 per cent. in the Tee-total Society, and 34·4 per cent. in the Perseverance. The Rechabites, who might be expected to occupy a creditable place nearer the Tee-totalers, are not in all cases, as appears from the returns, worthy of the name they assume.

Most of the sick clubs are also burial clubs; that is, a certain sum, varying from £2. to £10., is allowed on the death of a member. There are also in Preston seven societies acting only as burial clubs, but acting as such very extensively. Papers sent in from the secretaries to three of these clubs accompany this report*. From them

* The collector to a burial club, containing upwards of 5000 members,—a man whose intelligence is greatly superior to his rank in life, states, that while he believes such societies to be productive of much general benefit, he knows several instances in which they have been much abused. He is acquainted with cases in which *hired nurses* have speculated on the lives of infants committed to their care, by entering them into the clubs. Within the last few days, two young women proposed to him to enter a child into the society in which he holds office, offering to pay the weekly premium alternately. Upon inquiry, in conformity with his usual custom, as to the relation subsisting between them and the child, he learned that the child's mother was dead; and that *the infant itself was placed at nurse with the mother of one of these young women*. He also detailed the particulars of the case of an illegitimate child, which, having been in the care of its maternal grandmother, was removed, on her death, to the house of its father's relatives. Within a week of that removal, the child died (although, previously, it appeared to be in strong health); and under such circumstances as induced him, not only to refuse payment of the burial money from his club, but also to make such a representation of the affair to the officers of another club in which the child had been insured, as led them to make a similar refusal. No attempt was made to compel payment from either society.

The same "collector" has kindly furnished an account of the ages at death, of 400 members of the society to which he belongs, being the number removed by death during the last three years and three months.

Under 12 months old	69	17·22	} 62
From 1 year to 2 years old	79	19·77	
2 years to 3 " "	52	13·	
3 " " "	28	5·	} 38
4 " " "	20	5·	
5 " 10 " "	36	9·	
10 " 20 " "	23	5·77	
20 " 30 " "	17	4·22	
30 " 40 " "	23	5·77	
40 " 50 " "	25	6·22	
50 " 60 " "	14	3·5	
60 " 70 " "	10	2·5	
70 " 80 " "	4	1·	

In consequence of a suggestion made to him, the same person states it to be his opinion, that much advantage would be found by the adoption of a plan tending to increase the solicitude for the preservation of infant life; by which plan, a small

it appears that the present members belonging to the three societies are upwards of 23,400! and that the aggregate sum expended by them in funerals, or rather paid to claimants, amounts to £2460 yearly. In only one return are any particulars given as to the age or death of parties entered as members; and from that it appears that 64 per cent. of those members die under five years old. The returns do not afford the means of comparing this high per centage with that of the operative class generally. There are other circumstances connected with the operation of these clubs suggesting matter for grave consideration and inquiry. The same person may be entered into every society. The respectable secretary to one of the societies states, that he knows several instances in which the same person is on the books of three clubs. Thus, on the death of a child, the parent or other insurer may receive £16. 6s. 6d. (according to the payments of the three clubs now referred to), while the expense of interment with all befitting propriety should not exceed, and in fact seldom amounts to, £3. There is no restriction in any of the societies as to the admission of illegitimate children. If the weekly penny or halfpenny is paid for the stipulated period by either mother or father, he or she is entitled, on the demise of the insured, to all the benefits which the society promises. The burial clubs enrol 12 or 15 times as many members as the sick clubs, inducing the inference that the prospect to a poor person of support and assistance in illness is less desirable than the possession of £5., £10., or £15., on the decease of his child. Such a sum, too, being a larger one than the insurer, in most cases, ever before possessed at one time, or ever could hope to possess, except from such a contingency as that adverted to. Burial societies are, no doubt, susceptible of highly beneficial operation, especially as insuring the lives of fathers of families; and it is right to speak with reserve of their tendencies, in the absence of all positive proof of their injurious effects; but the facts above

weekly payment, commencing at, or soon after birth, and continued for 10, 12, 13, or more years, should ensure a liberal allowance for 1, 2, or 3 years, at a time when education would be most valuable to the child, and the necessity for sending it to the factory would, in a great measure, be obviated.

It is also admitted by the same authority, that a great improvement would be effected, if, instead of money being paid by the club at the death of a member, the funeral were undertaken by the society, and performed in a solemn and appropriate manner; but, nevertheless, to effect this, it would be necessary that *all* the burial societies should adopt the plan. Were only one or two to act upon it, insurances would soon be withdrawn from them, and transferred to those societies in which the old system of money payments was continued.

mentioned will be, to some minds, suggestive of painful ideas. When an insured child is attacked by sickness, the feelings created by the anticipated payment from the burial club, should it die, may sometimes be stronger than the anxieties for the preservation of its life. A respectable collector of cottage rents states in writing,—

“That he often fails to obtain the rent from cottagers, in consequence of sickness. The sickness of children is most commonly assigned as a reason for the non-payment. Almost all the children in families where he collects are members of burial societies, most commonly are subscribers of 1d. a-week each child. The children of the poor are, when sick, greatly neglected, and lost from want of due attention to cleanliness; and the poor seldom seek medical assistance for sick children except when on the point of death. One poor child, living in — street, the son of Thomas —, sits in a chair, or lies in a corner of a room, upon some bags of rags, without any covering upon him, and entirely neglected, both as

regards nursing and medical relief. Such cases he is constantly witnessing.”

Another collector of cottage rents states,—

“The poor people have often told me that they were unable to pay at that time; but when a certain member of the family,—generally a child,—died, they would be able to pay. I have felt much shocked at this, and I have told the people that it was very wrong to depend upon anything of the kind. Most of the children at the houses which I visit are in burial clubs.”

A lady, a friend of the author of this Report, states, that a young woman, whose services she required as a wet nurse, having a child ill, she offered to send her own medical friend to attend it. The reply of the nurse was,—“Oh! never mind, ma'am, it's in two burial clubs.”

Burial clubs.—Returns have been furnished by the respectable and intelligent officers of the “Preston Original Legal Friendly Burial Society, established 31st December, 1831.” From these returns the following table is formed.

Children between Two Months and Five Years Old.

Entered.		Actual Number on the Books.	Average Number on the Books during the Year.	Died.				Per Cent. on all the Deaths.
Years ending December 31st.	Number of Children.			Payable.	Per Cent.	Not Payable*.	Per Cent.	
1810	..	2,413
1811	1,515	2,812	2,627	167	6.35	10	1.52	7.87
1812	1,167	3,292	3,067	202	6.58	51	1.76	8.34
1813	1,549	4,110	3,716	253	6.81	32	0.86	7.67
		...	9,110	622	...	126
Average of three years	3,137	207	6.6	12	1.4	8.0

The following table shows the progressive increase of members since Dec. 31, 1840 :—

Years ending December 31st.	Under Five Years.		Above Five Years.		Total Members.
	Members.	Increase.	Members.	Increase or Decrease.	
1810	2,413	...	11,189	...	13,902
1811	2,842	429	12,675	+ 1,186	15,517
1812	3,292	450	12,703	+ 33	16,000
1813	4,110	818	12,560	— 143	16,700

The rules of the society prohibit entrance before the completion of eight weeks of age, and also after 55 years. They also exclude all persons who may “have any disorder or complaint upon them;” . . . “and in no case shall any member receive any benefit from this society unless 16 clear payments

(weekly) to the fund have been made previous to the day of their death.”

In the last printed report of the society it is stated that, at the close of 1843, the number of members was 16,700, and the funerals, during the year, 469. Calculating upon the mean of the number of members

* Having died within sixteen weeks of entrance.

between December 1842, and December 1843 (16,350), this mortality is about 2·9 per cent. The table has shown the mortality of infants in the society, for 1843, to be 6·8 per cent., and it remains to be stated, that the mortality among the members above five years (the mean of that portion of the society being 12,634, and the deaths being 216), is 1·7 per cent.; and that the general mortality of the society for 1843 (469 deaths "payable" + 32 "not payable" = 501) is 3 per cent.

The mortality of Preston has been already stated at 2·97 per cent. But this mortality includes a class of infants inadmissible to the burial societies, viz., those under nine weeks old, and also of adults beyond 67 years (55 years, limit of admission + 12 years, age of the club). In order, therefore, to compare the mortality of the society with that of the town, we must deduct from the latter the deaths under nine weeks and above 67 years: thus,

Total Annual Deaths.	Under 9 Weeks.	Above 67 Years.
----------------------	----------------	-----------------

1488 — (170 + 125) = 1193 deaths,
= 2·1 per cent. on a population of 50,000.

In this view the mortality of the burial society exceeds that of the general population by 0·6 per cent.; or, for 4 deaths in the town, there are 5 in the society.

In pursuing the comparison now attempted many other considerations must be taken into account. On the one hand sick and weakly persons are not admitted into the society, and the members who are above 5 years of age must consist chiefly of persons from 6 to 19 years old; on the other hand the general mortality of the society will be much affected by the large proportion of infant members = one-fourth of the whole.

Assuming, as we may, that the deaths in the society "not payable" appertain almost solely to children dying before "16 clear payments have been made for them,"—i. e. to children between two and six months old, a comparison, as regards this class of children, between the town and the society may be thus given:—

Annual average of deaths in the town (excluding those under 2 months and above 67 years) 1193:—deaths between 2 and 6 months, 125 = 10·4 per cent. on all the deaths.

Deaths in the club for 1843, 501; deaths between 2 and 6 months, 32 = 6·4 per cent.

A difference of this kind, though not perhaps to this extent, might be expected. The children entered into the society are, in a great measure, select lives; and, during the 16 weeks, they are sure to receive as much attention as can be bestowed upon them; while on the contrary, the uninsured

children will include all the weakly and precarious lives rejected by the societies.

The total of infant deaths in the society is, according to the table, 8 per cent. on all the children entered.

The deaths, in the general population, of the same class of children (between two months and five years) have been, on the average of the last six years, 629 annually. The census of 1841 stated the children under five to be 6885; and if we take from that number 300 as the proportion under two months old,—a deduction greater, probably, than the facts would require, we have a mortality (629 deaths in 6585 children) of 9·6 per cent. Having seen that infants dying in the town between two and six months are 10·4 per cent. in all the infant deaths, while the same deaths in the society are only 6·4 per cent., we should be led to expect that a similar proportion would appear when infant deaths from two months to five years in the town are compared with those of the society; the non-insured comprising the poorest and sickliest, and the insured being more choice lives, and that the facts would probably be represented thus:—

Mortality between 2 and 6 Months, calculated on Infant Deaths.		Mortality between 2 Months and 5 Years, calculated on Infant Population.	
Town.	Society.	Town.	Society.
As 10·4 :	6·4 :	9·6 :	5·9 :

But the mortality of the society instead of appearing as above, 5·9 per cent., is 8 per cent.!

The members of this burial society forming so large a portion of the whole population, it may be desirable to separate them from the general mass, and compare the mortality of the two parts respectively for the year 1843, estimating the population at 52,500, and taking the mortality from the table No. 4:—

Members of burial society	Deaths.
16,350	501 = 3 per cent.
Remaining population	36,150
	996 = 2·75 "

52,500 1,497

Let it be borne in mind, that, although the society has a very large proportion of infant members to account for its excessive mortality, the remaining population comprises all infants under two months, all the sick and ailing inadmissible to the society, and all those whose age exceeds between 60 and 70 years.

In 1841, the children in Preston under five amounted to 6885; they may now be calculated at 7200. If from this latter number are deducted those under two months old (300), the children unlikely, from their station, to be entered into any club (800),

and also sickly children, together with the offspring of the very lowest class (500), there remain 5600 children eligible to burial clubs, of whom two-thirds are entered in this club alone.

In glancing at the second table now given, it will be observed that the society in question has, latterly, derived its increase from children alone. The adults have already been entered; and henceforward children only will constitute the new members.

[We leave our considerate readers to draw their own inferences from these statements of facts. That infant life is most sinfully and cruelly sacrificed there cannot be a doubt. As dog-carts and chimney-sweeps, and blacklegs, have been held subjects worthy of special legislative interference, let us trust that another session of Parliament will not be suffered to pass by without a bill to regulate Burial Societies, and to protect the helpless infants of our manufacturing population against murder.—*ED. GAZ.*]

ON DISEASES
OF THE
LUNGS FROM MECHANICAL
CAUSES,
AND DR. CALVERT HOLLAND'S ACCOUNT
OF THEM.

By H. M. HUGHES, M.D.
Assistant Physician to Guy's Hospital.
(*For the Medical Gazette.*)

ALL who have paid much attention to the diseases of the lungs could not fail to be interested in the work of a physician directed to the investigation of the complaints induced by particles floating in the air, particularly when that physician had been so favourably situated for such inquiry, as, from his former works, Dr. C. Holland was known to have been. It was with much interest, therefore, that the papers of Dr. Holland, with the title above mentioned, were perused by me as they appeared in the *Edinburgh Monthly Journal*, and it was with equal, perhaps even greater interest, that they were examined since they have been printed in a collected form. The reader cannot, I think, fail to be pleased, and indeed, surprised, at the amount of time and labour which the author has evidently devoted to the subject generally; and more particularly at the large collection of statistical facts which he has presented to the world. It must, however, be acknowledged, that on both

occasions I have myself been disappointed to find that the author appears to entertain, or at any rate has expressed, no very clear views of the pathology of the affections to which the grinders are especially obnoxious. This deficiency, or want of completeness, in Dr. Holland's work, has doubtless arisen from the particular prejudice entertained by the grinders against inspection after death, and the consequent comparatively rare opportunities he has enjoyed of becoming familiarly acquainted with the morbid anatomy of their diseases. If it were otherwise, I feel assured from the great pains he has evidently taken in elucidating the subject, that Dr. Holland would have contributed more definite and decisive information respecting the appearances presented after death by the diseases on which he has written. It is generally known, and Dr. C. Holland must himself be perfectly aware, that the "pointers' asthma," or "grinders' rot," has been long, and very generally, considered to depend upon the disease now called chronic bronchitis, combined with dilatation of the bronchial tubes and emphysema of the lung, or dilatation of the pulmonary tissue. For though it may be true, as Dr. Holland has stated, that no author has particularly referred to the latter disease, in consequence of the imperfect acquaintance with morbid anatomy possessed by the individual, or existing at the time in which he wrote, it is now known to be almost necessarily induced by long continued and severe bronchitis or bronchial irritation. In the correctness of this opinion of the pathology of the complaint my own observation has led me entirely to coincide, though I am aware some physicians have expressed a different opinion, and believe that the diseases called the "grinders' rot" and "tubercular phthisis" are essentially identical. It is this question which I had hoped to have seen decided by the observation and necroscopic researches of Dr. Holland. It is this question, really very important in a hygienic point of view, upon which information is yet needed. It is the morbid anatomy of the diseases of the lungs or bronchial tubes, occurring among the grinders, that requires elucidation. It is this inquiry which I conceive may throw some additional light upon the still

obscure question of the pathology of tubercular deposition. But, unfortunately, it is this very question upon which the views of Dr. Holland appear to be indefinite, and his statements incomplete. His facts, indeed, appear to point in one direction, and his opinions in another. Should two persons or parties be engaged in public discussion upon the pathology of tubercles and of phthisis, and should they differ as to the cause of the deposition of these bodies, or the formation of this disease, each party might, as it appears to me, quote Dr. Holland in support of his particular views. The one might rest upon his obscurely expressed opinions, while the other might fairly advance his facts in support of an entirely different or even opposite line of argument. I am desirous not in any way to misrepresent the author, and shall therefore quote his own words in support of my assertion; I am, at the same time, particularly desirous that he should not regard his present commentator in the light of an unfriendly critic, but that, on the contrary, he should view him as one who highly estimates what he has already done, and who hopes hereby to invite him to extend his inquiries so as to render his own conclusions more definite, and to fix, upon the secure foundation of a large collection of facts, the morbid anatomy of the diseases of the lungs induced by mechanical causes.

The establishment of the true pathology of the complaint to which grinders are especially prone appears still to be a desideratum. The author states, indeed, that it presents two very distinct varieties; though he appears to regard both as only different forms of one and the same disease. Thus (p. 24), he says, "In some we have the leading symptoms of ordinary tubercular consumption; in others, extensive pulmonary degeneration, associated with striking modifications of the symptoms. In the one class, which will contain a majority of the sufferers, a distressing or urgent *cough* has generally existed for years; in the other the cough has been of much shorter duration, and slighter in degree, and has seldom excited the attention of the artisan until the breathing has become short and difficult.

"In the one class, the cough long precedes the disordered respiration; in the other it cannot justly be said to

follow; both are almost co-existent from the first. We will briefly sketch the difference observed in the two classes in the advanced stage of the disease. In the one, in which the cough is the early and prominent symptom, there is less emaciation of the body, a less tendency either to diarrhœa or to hectic, and the breathing is much more oppressed than in the other, and the expectoration is often exceedingly copious. The chest also exhibits considerable anterior rotundity, and even when there is unequivocal evidence of a structural change in the pulmonary tissue, the sound emitted on percussion is particularly sonorous. There is much greater suffering, and greater anxiety, depicted in the countenance in conjunction with these symptoms, than in those incorporated in the other class. And further, the tongue, and the mucous membrane, show, in most instances, a very slight departure from the condition of health. Diarrhœa is seldom present, except when chronic inflammatory mischief has long existed in some of the important abdominal viscera." In page 27 he says, of the same form of complaint, "We have no hesitation in stating that the sound (on percussing the chest) is frequently much louder than in health. In all the individuals in whom we have found this particularly marked, shortness of breathing, and a distressing cough, have always been present. The cough has generally existed for years. On this subject we speak from extensive investigations. On applying the ear, or stethoscope, to the chest, the respiration is exceedingly loud and bronchial in its character. The ordinary sounds of inspiration and expiration are sometimes not heard, or very indistinctly, and this peculiarity of the respiration is often detected, in various degrees, throughout both lungs, and when once heard the peculiarity of it cannot be mistaken. Accompanying this symptom is the prominence of the chest, a condition which is very obvious, when compared with the development of the thorax in cases where the pulmonary degeneration is not associated with this kind of respiration. Among the grinders suffering from the occupation, the aged—that is, persons from forty to fifty-five years old,—generally present this symptom if they have been long subject to violent cough." "In

the other class (he says, page 25,) in which the cough is scarcely recognised by the artisan previously to the breathing becoming short, the body rapidly emaciates, the expectoration is less copious, the chest is somewhat contracted and flat, and on percussion emits a duller sound, though often to a considerable extent sonorous, than when the cough has long preceded the dyspnoea. In both classes tubercles are found in the lungs, though by no means invariably in cases in which the cough was the principal distressing symptom for years."

Now, it must be obvious to all who are conversant with the symptoms and physical signs of diseases of the lungs on a large scale, and who are also in the habit of examining a large number of bodies after death, that Dr. Holland's former class of cases, which, he says, "will contain the majority," are in fact examples of chronic bronchitis, dilated tubes, and emphysema of the lungs: the very disease which has hitherto been generally supposed to constitute the "grinders' rot;" but of which there has not hitherto appeared any evidence so decisive as that afforded by Dr. Holland. This evidence is certainly not the less important and conclusive because it appears to have been accidental and unintentional. I say unintentional, because Dr. Holland seems to consider both classes of cases as merely different forms of phthisis, and quotes Dr. Hastings' work on bronchitis, to show that they vary from the chronic form of that complaint. The view herein entertained of the nature of the first class of cases is confirmed by the author having observed after death "enlargement of the bronchial tubes and an expansion of the pulmonary tissue as among the most important structural changes."—(Page 12). It is true, as I have previously quoted, he says, "in both classes tubercles are found in the lungs," but he adds, "though by no means invariably in cases," &c. &c.; and in a former part of his work (p. 12), he states, "This form of complaint is no *certain* protection against the inroads of further pulmonary degeneration, as tubercles, hepatisation, or other structural changes." That he believes the grinders are especially liable to phthisis seems evident from the following sentence (page 14), "Whatever may be the

cause of tubercles, they are found in numerous cases in the lungs of grinders, and can be traced to the inhalation of dust."

Yet at other parts of his work, he appears clearly to consider the characteristic peculiarities in the diseased lungs of grinders to consist in dilatation of the tubes and emphysema of the pulmonary tissue. It is to be lamented that the work is not better arranged, that it contains so many repetitions, and that the pathological views of the author are so uncertainly, variably, and indefinitely expressed. He is clearly in error when he states (p. 45), referring to the first class of cases, "The association of these symptoms can be common occurrences only where the healthy and robust constitution is exposed to the inhalation of gritty particles." He appears, indeed, himself afterwards to allow that they may arise independently of such causes, as he says, when speaking of saw grinders (p. 95), "In this branch there are only four affected with the disease peculiar to grinders, and these cases are more likely to have arisen from exposure to wet and cold than from the inhalation of dust." I can myself assure the author, from oft repeated experience, as not a week, or scarcely a day, passes but such cases come under my notice, that not only are persons who are exposed to the inhalation of particles floating in the air, whether mineral, animal, or vegetable, liable to precisely similar symptoms, and present exactly the same physical signs, but that they occur as the very common consequences of the bronchial affection following measles, and more especially of whooping-cough in childhood.

Dr. C. Holland, while speaking of the morbid appearances presented by the lung, mentions some which he regards as peculiar to "grinders' phthisis." Previously, however, to any real peculiarity being recognized and acknowledged to exist therein, it should be clearly stated whether he has or has not, in his account, conjoined the appearances presented by *each of the two classes of disease* which are essentially distinct. He mentions, for example, the frequent occurrence of pleuritic adhesions and other indications of by-gone inflammatory attacks. These are, according to general experience, exceedingly common in ordinary tuber-

cular phthisis, but comparatively rare in chronic bronchitis. Again, he speaks of the great venous congestions occurring generally throughout the lungs, or in defined portions of these organs. This, I conceive, will be generally acknowledged to be constantly met with in bronchitis and emphysema; but not to be very commonly seen in genuine phthisis. No mention is made of the state of the heart. This is the more remarkable, as dilatation, particularly of the right side of that organ, almost universally co-exists with the former complaint, but is not noticed as a common occurrence in the latter.

The conclusions which may be derived from Dr. Holland's facts, then, appear to be, that grinders are liable to two forms of disease, presenting remarkably different symptoms and physical signs during life, and probably followed by various morbid appearances after death. Both these forms of complaint, however, Dr. Holland seems to regard as only varieties of phthisis. In both he speaks of "cavities and degeneration of the lungs."

Considerable darkness and doubt, notwithstanding the extended labours of the author, still involve the true pathology of the disease familiarly known as "pointers' asthma" or "grinders' rot." This darkness I would respectfully invite Dr. Holland, by enlarging the sphere of his inquiries, to assist in dispelling; this doubt I would solicit him, by extending his observations, to remove, as from his position among the grinders of Sheffield, the interest he has already exhibited in their welfare, and the investigations in which he has already engaged, he appears to be especially fitted for the purpose. By effecting this, the author may not only render essential service to the pathologist in removing a portion of the uncertainty which, notwithstanding all that has been written, still appertains to the site and morbid anatomy of tubercles, but he may possibly, and not very improbably, confer a very important benefit upon mankind at large, by clearly establishing, from facts collected upon a very large scale, some of the exciting causes of tubercles, and some of the circumstances which oppose or prevent their deposition.

To effect this purpose large numbers and frequent and minute dissections

after death are absolutely necessary. The direction of the inquiry which I take the liberty of submitting to the consideration of the author will be indicated by the succeeding observations.

It has been remarked by others, and it has long been observed by myself, that though in tubercular phthisis certain small defined portions of the lung may be affected to a very great extent with emphysema, yet that when the emphysema is general and the tubes are dilated, the lungs are found especially free from tubercles. So commonly, indeed, has this fact been presented to my notice—so very rarely, among the vast number of lungs that I have myself examined, or seen examined after death, have I seen tubercles in the lungs to coexist with general emphysema of those organs, that I have long been in the habit of regarding the presence of the latter almost in the light of a safeguard against the former. Persons who during childhood have suffered severely from pertussis, and who during their youth and manhood have been more or less frequently troubled with cough and bronchorrhœa, are, as age advances, affected, not with tubercular, but with emphysematous lungs; or what is commonly called asthma. With this are generally combined dilatation of the bronchial tubes, and enlargement of, particularly the right side of, the heart. The same may, I believe, be said of persons affected from their youth or infancy with contorted spine and consequent malformation of the thorax, who have been supposed, but I think quite erroneously supposed, to be especially prone to consumption. The complaint of which they most commonly die is not consumption, but emphysema, and consequent dilated heart, ascites, hydro-thorax, and pulmonary apoplexy; the whole of which appear to be in great measure the purely mechanical effects of obstruction to the passage of blood through the emphysematous lung; a condition which, at least in many cases, is itself a simple mechanical effect of long-continued bronchial disorder.

I have stated that the presence of long-standing bronchitis and emphysema, has very rarely indeed, in my experience, been associated with tubercles. I trust that it will not hence be inferred that I suppose that the induction of emphysema (if even it could be as-

surely induced by an artificial process), is followed by the removal of tubercles already existing, and more especially that I at all believe, according to the asserted theory of a metropolitan physician, that the pressure of a lung increased in bulk by the enlargement of its cells ever does, or can, cause the walls of tubercular cavities to adhere, and thus lead to the cure of advanced consumption. The appearances so confidently brought forward in support of this dogma can be sufficiently and satisfactorily explained, quite independently of such an improbable supposition.

In conclusion, then, I will inquire of Dr. C. Holland—

1st. Whether in the class of cases which he has observed to be accompanied with emphysema of the lung and dilatation of the bronchial tubes, tubercles *generally* exist in the lungs.

2dly. If tubercles *ever* exist when the emphysema is universal.

3dly. Whether what he has termed "cavities and degeneration of the lung" in these cases, really appertain to the pulmonary tissue itself, and whether the cavities may not possibly have been sections of the bulbous extremities of dilated tubes, instead of tubercular abscesses or small vomicae, from which I know by experience they are not easily distinguishable, without very minute examination.

4thly. Whether tubercular, or what he denominates "hereditary phthisis," is really *more*, or whether it is *less*, common among grinders than among other persons *placed in precisely similar circumstances in respect to food, clothing, confinement, position of the body, and hereditary predisposition*.

The whole of these, it will be at once seen, resolve themselves into the single question of the constant irritation of the bronchial lining membrane from mechanical causes, and the consequent production of dilatation and emphysema, being favourable to, or actually opposing, the deposition of the bodies called tubercles, or other unorganizable matter, upon the presence of which in the lung true phthisis essentially depends.

That the existence of such irritation does not necessarily prevent the development or softening of these bodies or this matter when already existing in the lungs, is sufficiently proved by the facts

stated by Dr. Holland. Independently, therefore, of any other evidence than that afforded by his book, it is clear that the induction of catarrh or bronchitis cannot be properly or consistently prescribed as a remedy, and much less as a cure, for phthisis pulmonalis.

MEDICAL EVIDENCE IN BELANEY'S CASE.

To the Editor of the Medical Gazette.

SIR,

WILL you do me the favour of inserting this letter in as early a number of your journal as may be convenient; it is an answer to one I have just seen, and which appeared in the Herald of the 17th inst., purporting to be a review of the medical evidence given by myself and Dr. Thomson at the late trial of Belaney, and accusing us of *having allowed ourselves to be directed by general evidence, of having assumed wrong premises, and drawn conclusions from them which were not warranted*: three charges, sufficiently grave and serious to call for a reply, especially as they are put forth by a medical professor under the form of a scientific dissertation. I can, and do, sympathise with the Rev. Belaney, and hope that no word or act of mine will give a tone to the general impressions which are everywhere formed respecting the unfortunate death of his brother's wife; and I assure him that I was actuated by the same feelings when I entered the Court to give evidence at the trial, being convinced that general reports neither did, nor could, come within the scope of my inquiries, which had reference merely to the *medical facts*; and for the purpose of arriving at these, and removing every tittle of doubt or objection which ingenuity might raise against them, I had instituted experiments under every variety of form and circumstance, the results of which, and not of any readings or hearsay, I detailed honestly and as clearly as I could to the jury, never allowing myself for one moment to be swayed by a double-meaning question, or by any party feeling; and it must also be remembered that I was not unaccustomed to such investigations, but that the circumstances of my position had for many years demanded an almost daily examination into them.

Among the wrong conclusions with which Dr. Glover charges us, are the following:—He says, I had no right to assume that the *cry* of Mrs. Belaney was a *shriek*, or that it was the effect of the poison. Now I do not know that I have anywhere made such an assumption. It is merely asked of me, whether animals, under the influence of prussic acid, do not cry out? To which I answer—*yes*, that it is a constant effect: and then it is inquired of me whether, after this cry, there would be a possibility of walking to bed and telling the cause of the disaster? To which I reply, “*Certainly not!* for after the shriek all sensibility and volition cease.” And Dr. Thomson confirms my statement. This was no answer given hastily and inconsiderately, but sought for amidst multitudes of experiments and observations; nor is it in any way invalidated by the case quoted from Christison, or, indeed, by any case within my knowledge that has ever been upon record. There can be no doubt, as this and other cases show, of a capability of speaking after the exhibition of the poison; but this is not the argument; it is, whether there can be conversation *after the shriek*—which I maintain is impossible. With respect to the other question, whether Mrs. Belaney’s cry was a mere call to her husband, or a scream resulting from the poison, I have never offered an opinion, although Mr. Garrett stated in his evidence that Belaney told him it was a *scream*.

Again, according to the husband’s statement, Mrs. Belaney called the drink *hot*; and I am asked, if prussic acid has a hot taste? and reply, “No; that its taste is bitter.” I have tasted it again and again, and on two occasions in quantities sufficiently large to produce faintness; yet Dr. Glover maintains, by an unnecessary, an inapplicable, and a most unlearned dissertation upon the chlorides, bromides, and iodides of cyanogen, that it *must* be hot,—though I cannot see how this affects the matter of fact arrived at by myself and another, who is nearly the only individual who has lived to record that *its taste is inexpressibly bitter*.

In next part of the review, Dr. Glover pronounces our answers to be an outrageous piece of cruelty. It was known that Belaney, although he called himself a medical man, used no efforts to

recover his wife, and we are asked whether the remedies for prussic acid are generally known in the profession? To which we reply, that they should be, inasmuch as they are everywhere taught; and I think that we were warranted in making such a reply, when it is remembered that for sixteen years or upwards they have been publicly and emphatically taught in our schools, and are constantly being brought before the profession in one form or another; that we have professed works and journals, and charts, to teach them to us; and if Dr. Glover’s “old and young acquaintances, who are in active practice,” do not happen to know them, it can surely never palliate, or in any way remove the culpability of the charge of gross neglect and ignorance; nor can it be admitted as an argument of the universality of such ignorance: if it did, Heaven knows, there is necessity enough for reform in our profession; but most singularly, when Dr. Glover finds it convenient to make Belaney a judicious looker-on, he argues for the propriety of his conduct, and says, that when he stood by ready with his lancet, he was acting in accordance with the views of Orfila, Christison, Magendie, and others. And why, may I ask, did he not further act in accordance with common affection and common honesty, and try to save her? To crown the whole of this part of Dr. Glover’s review, he tells us that *we do not know the remedies ourselves*; notwithstanding the whole tenor of our evidence, that she might have been saved.

Lastly, as regards our opinion, that a smell would exist for some time in the room where prussic acid had been spilt, Dr. Glover expresses his dissent *in toto*, although it has been stated that my conclusions were drawn from experiments made under circumstances as nearly as possible like those of the case in question; and in conclusion, without staying to comment on the pseudo-scientific character of the review, meant evidently to catch the popular ear. I will merely express a wish that it had been written with a more “*conscientious spirit*.”—I am, sir,

Your obedient servant,

HENRY LETHEBY, M.B.

Lecturer on Chemistry at the
London Hospital.

12, Tredegar Square, Oct. 31, 1844.

EXPERIMENTS ON THE FORMATION OR SECRETION OF CARBON BY ANIMALS,

THE DISAPPEARANCE OF HYDROGEN AND
OXYGEN, AND THE GENERATION OF
HEAT DURING THE PROCESS.

To the Editor of the Medical Gazette.

SIR,

IN a former communication I stated how experiments may be made which prove that animals secrete carbon. On this occasion I purpose describing experiments from which it may be inferred that this formation or secretion of carbon is accompanied with the disappearance of hydrogen and oxygen, and the generation of heat.

Two young mice, the one weighing 210 and the other 218 grains, were placed in a round wire trap, five inches in diameter, and supplied with bread and water only. During the first six weeks they were supplied each day with 110 grains of bread, slightly moistened with water, and containing 29.7 grains of carbon. The mean weight of carbon in the respired air

First twenty-four hours . . .	8.9	cubic inches	per hundred,	213.6	cubic inches	per diem.
Second twenty-four hours . . .	6.6	"	"	158.4	"	"
Third twenty-four hours . . .	5.4	"	"	158.4	"	"
Second twenty-four hours . . .	5.0	"	"	60.0	"	"

ing 73.4 grains of carbon. The weight of the two animals was, after the first thirty hours, 205 and 217 grains respectively; and, at the expiration of the eighty-four hours, 178 and 194 grains; the one having lost 6.4, and the other 7.4 grains in weight.

For six days from this period they were supplied three times a day with as much bread, in its usual state of moisture, as they could eat; and as

given off during this period was 38.8 grains per diem. The animals increased in weight respectively to 242 and to 268 grains.

Desirous of reducing the weight of the carbon comprised in these animals as low as possible, without depriving them of life, they were placed under experiment for eighty-four hours; fed daily with only 24 grains of bread, made into a thin pulpy mass with 50 grains of water,—a mixture which has a very reducing effect upon these kind of animals. They were also placed between the hours of 5 A.M. and 10 P.M., at intervals of half an hour, near the top of an inverted glass jar, contents 206 cubic inches; atmospheric communication being cut off by mercury. During the first day they were kept in this situation for half an hour, and during the rest of the period for an hour each time.

In the morning, when the animals were in a state of repose, the volume of carbonic acid they gave off was comparatively small. In the night, when they were always most active, the volume was comparatively great. The mean volume was, for the

Total . . . 561.6 cubic inches, containing much water as they would lap from a drop tube. In the six days they consumed 780 grains of bread, containing 210.6 grains of carbon, and from 100 to 110 grains of water; increased in weight to 256 and 276 grains, and imparted to the atmosphere 249.7 grains of carbon. The increase in weight, and the weight of carbon in the respired air, in each twenty-four hours, was as under:—

	Weight of mice.	Carbon in respired air.
First twenty-four hours . . .	227 and 242 grains	33.9 grains.
Second twenty-four hours . . .	230 and 248 "	39.5 "
Third twenty-four hours . . .	240 and 255 "	43.4 "
Fourth twenty-four hours . . .	246 and 259 "	43.3 "
Fifth twenty-four hours . . .	252 and 268 "	44.0 "
Sixth twenty-four hours . . .	256 and 276 "	45.6 "

249.7 grains.

At the end of the sixth day the heavier animal, which was of comparatively quiet habits, was killed, by placing it in a small tube standing over mercury. It was then exposed to a temperature varying from 200° to 220°

for two days, by which it was reduced in weight to 86.6 grains. The whole animal was reduced to one mass in a mortar, and an average sample, on being analysed with oxide of copper, gave, for the constitution of the

DRY MOUSE.		
	Per cent.	Whole weight.
Carbon . . .	53.02	45.91
Hydrogen . . .	7.19	6.23
Oxygen . . .	18.50	16.02
Nitrogen . . .	11.19	9.69
Ashes . . .	10.10	8.75

100.		86.6

MOUSE BEFORE DRYING.		
Carbon . . .		45.91
Hydrogen and oxygen as in water . . .		207.45
Hydrogen in excess . . .		4.20
Nitrogen . . .		9.69
Ashes . . .		8.75
<hr/>		<hr/>
		276.

The other animal, which was of active habits, was allowed to remain at rest for two days, having as much bread and water as it would consume, but did not increase in weight. It was afterwards supplied with a very sparing quantity of food, consisting of ten grains of bread and ten grains of water

each day, for four days; and kept one day and six hours without any food. During this period it was kept, as above described, within a glass jar, atmospheric communication being cut off by mercury, and gave the following results:—

	Weight of mouse.	Decrease.	Carbon in the		Increase.
			Food.	Respired air.	
First twenty-four hours . . .	235	21	none	2.13	21.3
Second twenty-four hours . . .	217	18	2.7 grs.	15.9	13.2
Third twenty-four hours . . .	196	21	2.7 "	11.8	9.1
Fourth twenty-four hours . . .	182	14	2.7 "	7.7	5.0
Fifth thirty hours . . .	169	13	2.7 "	7.0	4.3
<hr/>		<hr/>	<hr/>	<hr/>	<hr/>
			10.8	63.7	52.9

The animal in this reduced state was killed, and dried in the manner above

described, when its weight was 51.5 grains, and was constituted of—

DRY MOUSE.		
	Per cent.	Whole weight.
Carbon . . .	43.70	22.50
Hydrogen . . .	5.82	3.00
Oxygen . . .	20.72	10.67
Nitrogen . . .	13.36	6.88
Ashes . . .	16.40	8.45
<hr/>		<hr/>
100.		51.5

MOUSE BEFORE IT WAS DRIED.		
Carbon . . .		22.50
Hydrogen and oxygen as in water . . .		129.50
Hydrogen in excess . . .		1.67
Nitrogen . . .		6.88
Ashes . . .		8.45
<hr/>		<hr/>
		169.

The experiments were conducted in the following manner. All foreign supply of food was cut off by keeping the animals in a wire trap, out of which they were never taken, except for the purpose of being weighed, which was performed in a few minutes. They were fed with average samples of crust and crumb of bread, weighed when new, and kept in its moist condition under an inverted glass, which also covered a cup containing water. These samples of bread were not separately analysed; but the highest per centage of carbon obtained by analysing other samples of this kind of bread, was calculated for in these experiments. The weight of carbon in the respired air was obtained by calculation from the volume of carbonic acid, which was determined by removing with a syringe samples of the air from within the inverted glass jar, at the end of each period of the animals' confinement in the limited atmosphere, transferring this

air to apparatus standing over mercury in which $\frac{1}{1000}$ of its volume could be read, absorbing the carbonic acid by liquor potassæ, making the necessary barometric and thermometric corrections, and an allowance for the carbonic acid in the common atmosphere of $\frac{1}{2000}$ of its volume*. The weight of the animals was obtained by placing the trap in a gauze bag, in which they were separately weighed after removing the trap. The trap was then cleaned, and the animals returned to it again. The weight of each element was determined by a method of analysis which combines expedition with ease and accuracy.

By placing the results thus obtained in tabular forms, those features which more particularly claim attention at the present time will be brought more prominently before us.

* Animals and birds die in a few hours on being kept in an atmosphere from which all the carbonic acid is immediately removed.

	Weight of mice. grs.	Weight of bread. grs.	Weight of Carbon in		
			Bread. grs.	Respired air.	Increase. grs.
At the commencement . . . }	210 }				
	218 }				
After six weeks' moderate supply of food . . . }	242 }	4620	1247	1630	383
	268 }				
After eighty-four hours' limited supply of reducing food . . . }	178 }	84	22.7	73.4	50.7
	194 }				
After six days' abundant supply of food . . . }	256 }	780	210.6	249.7	39.1
	276 }				
After five days' and a quarter sparing supply of food. One mouse . }	169 }	40	10.8	63.7	52.9
Total increase 525.7					

From what is shown in this table it may be inferred that these animals have the power of secreting carbon; and that this power is constant whether the animals are kept upon a sparing or plentiful supply of food. The total weight of carbon secreted during the period they were under experiment forms 99 per cent. of their greatest, and 141 per cent. of their least united weights, and when the weight of the carbon in the respired air is compared with the weight of the carbon in the food, they are to each other—

Carbon in the food 100
Carbon in the respired air 136

That this secretion of carbon is effected by the disappearance of hydrogen and oxygen, is inferred rather than directly proved by the experiments; we cannot, as with plants, in proving that carbon and nitrogen are vegetable secretions, keep the animals in the same

limited atmosphere for many days or weeks together. When the evidence, however, sought out of these experiments is taken in conjunction with that of other experiments, which proves that the change effected upon the atmosphere by animal respiration is principally confined to that of changing a volume of atmospheric oxygen into a volume of carbonic acid, we may safely draw the inference, that some of that hydrogen and oxygen which forms a portion either of the food or of the animal itself, or of both, undergoes some process of natural chemistry, having this secreted carbon as a result. This will become fully illustrated by calculating for the weight of the elements in the two animals at the different periods, agreeably to the results obtained by the analysis, and by drawing lines of comparison in the following manner, viz.

The two mice at the commencement.	Carb. 71.2.	Hy. and ox. as in water 316.6.	Hy. in excess 6.1.	Nitr. 17.9.	Ash. 16.2.	Total 428.
After six weeks	84.8	382.4	7.7	17.9	17.2	510
After eighty-four hours	49.5	286.4	3.7	15.2	17.2	327
After six days	88.5	399.5	8.1	18.7	17.2	235
After five days and a quarter, one mouse .	22.5	122.5	1.7	8.4	8.4	169

Which upon a recapitulation of the carbon, the hydrogen, and oxygen, as in water, and the hydrogen in excess, gives for the

First six weeks' moderate supply of food

	Carbon.	Water*.	Hydrogen.
At first Animals	71.2 }	316.3 }	6.1 }
Bread	1247.0 }	3231.0 }	9.2 }
Water		630.0 }	
At last Animals	84.8 }	382.4 }	7.7 }
Respired air	1639.0 }		
	+ 396.6	— 3797.9	— 7.6

* A considerable portion of water would evaporate from the bread when in the trap, and before it was eaten.

Eighty-four hours' reducing food.

At first	Animals	84·8	} 107·5	382·4	} 610·4	7·7	} 8·0
	Bread	22·7		58·0		·3	
	Water			170·0			
At last	Animals	49·5	} 122·9		} 286·0		} 3·7
	Respired air . . .	73·4					
			+ 15·4		— 324·4		— 4·3

Six days' abundant supply of food.

At first	Animals	49·5	} 260·1	286	} 932	3·7	} 5·3
	Bread	210·6		546		1·6	
	Water			100			
At last	Animals	88·5	} 338·2		} 399·5		} 8·1
	Respired air . . .	249·7					
			+ 78·1		— 532·5		+ 2·8

Five days' and a quarter very sparing supply of food.

At first	Animals	42·6	} 53·4	192·6	} 260·6		} 3·9
	Bread	10·8		28			
	Water			40			
At last	Animals	22·5	} 86·2		} 129·0		} 1·7
	Respired air . . .	63·7					
			+ 32·8		— 131·6		— 2·2

From these results we may fairly draw the inference that the secretion of carbon in animals is accompanied with the disappearance of water and hydrogen; and these results would have appeared in a still more favourable light if the excrementitious matter had been taken into account, which in these experiments was always mixed with small crumbs of bread. This matter was not analysed; but its quantity, when the animals are plentifully supplied with food, forms about seven per cent. of the weight of bread, and contains about thirty-five per cent. of its weight of carbon. It formed a considerable proportion of the weight of the food consumed during the eighty-four hours the animals were supplied with food of a reducing tendency, but

a very small proportion when the animal was fed with dry food. If we add to the plus quantity of carbon in the above table, as much carbon for that contained in this matter as will make the weight of that secreted during the first six weeks 500 grains, during the eighty-four hours 24 grains, during the six days 96 grains, and during the five days and a quarter 35 grains, we may consider this body fairly represented in these experiments.

Until we have other experimental evidence which more fully proves that when animals secrete carbon, hydrogen disappears in a proportion exceeding that in which it forms water, let us in this instance make our calculation as if water only disappeared: we shall then have in the—

	Hy. and ox. in the animals, bread and water.	Carbon secreted therefrom.	Hy. and ox. passed off by other means.
In the first six weeks	3798	500	329 grains
In the eighty-four hours	324	24	300 „
In the six days	533	96	437 „
In the five days and a quarter, one mouse .	131	35	96 „

The secretion of carbon resulting from the disappearance either of hydrogen and oxygen in the proportions in which they form water, or from the former in a higher proportion, our knowledge of the specific heats of bodies leads us to infer that heat will be generated during the secretive pro-

cess; and by calculating for the heat generated by the formation of the carbonic acid in the respired air, and for that generated by the formation or secretion of the carbon in these experiments, we have the two heats bearing the following proportions:—

	Heat generated by the formation of carbonic acid.	Heat generated by the secretion of the carbon.
In the six weeks	100	325
In the eighty-four hours	100	346
In the six days	100	412
In the five days and a quarter	100	590

Hence we infer that these animals generate from three to six times the heat by the formation of the carbon they secrete, as by the formation of the carbonic acid they respire; and that this secretion of carbon, and consequently, generation of heat, is influenced by the quality and the quantity of food, exertion, and quiet and active habits.

I might further observe that since all my experiments, whether made with animals or with birds, prove that car-

bon is secreted by them, in proportions varying with the circumstances under which they are placed, I conclude that the formation or secretion of carbon is essential to the support of animal life, and that it is a great source of animal heat.

I am, sir,
Your obedient servant,
ROBERT RIGG.

Greenford, Middlesex,
Sept. 27th, 1844.

POINTS OF PRACTICE.

By A. L. WIGAN, M.D.

OFFENSIVE BREATH.

To the Editor of the Medical Gazette.

SIR,

AMONG the diseases unattended by pain and danger, there is not, perhaps, one which gives annoyance so severe, and unhappiness so intense and complicated, as that selected for the subject of the present letter. I have known it lead to suicide, by rendering the sufferer disgusting where he most wished to excite interest and affection. Long does the unhappy man resort to useless stratagems, and *hope against conviction* that his malady is not perceived by others—and no one ventures to tell him of a defect so humiliating. He dares not ask advice lest he should communicate the knowledge of the fact, where he still hopes it has not been perceived, so year after year he goes on in the disheartening consciousness of degradation, when perhaps the shame and anxiety might have been relieved in a single hour, had he had the courage to make an open confession to a man of experience.

It is obvious that a great many of the causes of this vexatious annoyance are quite out of the reach of remedy. It is unnecessary to enumerate them, as they will suggest themselves to every one.

Faithful to the plan I announced in my first letter, I shall confine myself to the diseases and defects for which I can suggest a positive and efficient remedy. One of the most common causes of offensive breath, and by far the most disgusting, is removed with the greatest ease. I cannot recollect to have ever met with a notice of it, and the dislike of the patient to complain, and the surgeon to inquire, may perhaps explain this.

The tonsils, then, are subject to a peculiar abscess, if it may be so called—the tumor is of the kind called, formerly, melicerous steatoma, but of its modern name, in these days of incessant change, I know nothing. Many years elapse in its progress to maturity, during which the only annoyance experienced is from the mechanical obstacle to deglutition, and to the command of the voice. From time to time inflammation takes place, and the usual inconveniences are felt of quinsy, not going on to complete suppuration. The glands increase in size on each attack, but generally subside again into their usual state.

After one of the attacks, however (several weeks after the active symptoms have disappeared), a small perforation is formed by ulceration, perhaps not larger than the head of a pin. From time to time, a small particle of the contents of the sac escapes, and produces the most horrible stench. I

have more than once known a patient faint, from the disgust and sickness produced. This is renewed time after time, month after month, and year after year, making his life an intolerable burthen. The act of swallowing will sometimes press out a portion larger than usual, and this will produce long-continued vomiting.

From the humiliation felt at communicating with a friend or acquaintance, the sufferer usually resorts to a quack doctor, who, aided by a quack dentist, contrives to fleece him pretty handsomely. When the two have drained his purse effectually, he buys pastilles and lozenges, and cheats himself into the hope that the hot spices overcome the offensive odour.

The remedy is so obvious, that I should hardly think it necessary to name it, but for the purpose of introducing to the notice of the reader a little instrument which I was in the habit of using for many years, and which very much facilitates the management of this and similar enlargements of the tonsils; more especially in the aggravated form of *cynanche tonsillaris*, where it is difficult to open the mouth. I have drawn it exactly of its proper size, and think it is much safer and much more manageable than the common pharyngotome. To poke about in the dark with a pointed instrument, and *push from you* to open an abscess, is sometimes a very awkward affair, and to the man who has not *eyes at the ends of his fingers* (which I believe is the case with the greater number of us), it is extremely embarrassing. With the instrument represented in the margin, it is scarcely possible to have an accident, even where the mouth can be opened only wide enough to admit the introduction of it edge-ways.

In the melicerous abscess which gives rise to offensive breath, this difficulty does not exist. The reason why the hook, *cutting on the inner edge only*, is so useful, is, that sometimes there are several sacs, or divisions in the sac, and when the tumor is rendered flaccid by the escape of a part of its contents, it is very difficult to pierce it with the lancet or pharyngotome, whereas, with the instrument here described, you have only to catch any portion and pull towards yourself, to make any extent of incision you may require.

venient to him to procure ice, let him dissolve some in it, and use water equally cold as a daily gargle. The addition of a little tincture of myrrh is useful.

In all cases where the tonsils are liable to disease, let him make a practice of going with his neck entirely open for as large a portion of the twenty-four hours as his domestic arrangements will allow.

A. L. WIGAN.

ON THE BEST METHOD
OF
FINDING THE SPECIFIC GRAVITY
OF POWDERS.

—

To the Editor of the Medical Gazette,

SIR,

IN making some experiments lately upon the specific gravity of different powders, the following plan seemed to possess some advantages, in point of convenience, over the one usually adopted. The great objections to the extremely ingenious method proposed by Sir J. Leslie, are the trouble and risk of breakage in operating with a slender glass tube, above thirty inches long, and the somewhat complicated calculations required by it; both of which appear to be much lessened by the plan which I have employed.

The great difficulty in estimating the specific gravity of powders has always been occasioned by the air which is mechanically mixed with them, and the consequent uncertainty as to the actual volume of the powder itself. If the powder to be examined be immersed in water, and the vessel containing it is put under the exhausted receiver of an air-pump, the air, being relieved from pressure, rises in bubbles through the water, and leaves the powder free. The method of applying this principle is very simple. Take a

common specific-gravity bottle, capable of containing 500 or 1000 grains of water, and counterpoise it. Then take any quantity, 50 or 100 grains, of the powder to be examined, and introduce it into the bottle, and fill this with distilled water. Place it under the air-pump receiver, and exhaust the air. When the escape of bubbles ceases, it will be found that the bottle is not full. Fill it, and weigh it. By subtracting the weight of the powder from the total weight, the quantity of water in the bottle is found; and by subtracting this from the quantity which it is capable of holding, we ascertain the space unfilled with water, which is therefore occupied by the powder. Then, as the weight of the deficiency of water is to the weight of the powder, so is the specific gravity of water to the specific gravity of the powder.

To illustrate this by an example: a specific-gravity bottle was taken, capable of holding 500 grains, and 50 grains of iodine were introduced. The bottle was then filled with water, but was weighed previously to being put under the air-pump. It weighed 539 grains. It was then placed under the receiver, and the air exhausted. On the addition of water, to fill it up, it weighed 540·75 grains. As the powder itself weighed 50 grains, there were 540·75 grs.—50 grs.=490·75 grs. of water in the bottle; and the powder, therefore, occupied the space of 500 grs.—490·75 grs.=9·25 grs. of water. Then,

Wt. of Water.		Wt. of Iodine.		Sp. gr. of Water.		Sp. gr. of Iodine.	
As	9·25 grs.	:	50 grs.	:	1	:	5·4

This result differs from that of Gay Lussac, who found it to be 4·948; and his statement is usually adopted by chemists; but it differs much less than that of Dr. Thomson, who found it to be only 3·084. On comparing the weight found before exhausting the air, it will be seen that the presence of

a small quantity might materially alter the result. In the first experiment, the contents of the bottle weighed 539 grains, which gives 489 grains as the weight of the water; and this subtracted from 500, leaves 11 grains as the quantity of water displaced by the iodine. Then,

Wt. of Water.		Wt. of Iodine.		Sp. gr. of Water.		Sp. gr. of Iodine.	
As	11 grs.	:	50 grs.	:	1	:	4·55

If the powder is very light, as, for example, finely-powdered charcoal or magnesia, it is much better to put it into the bottle, and exhaust the air previous to the addition of the water. This may be afterwards added, and the bottle should be replaced upon the air-pump, to remove any small quantity of air which may be thus introduced, and then weighed. The necessity for this

precaution was rendered evident in examining charcoal; for, on commencing the exhaustion, the mixture frothed up so as to prevent the completion of the experiment. It was easily managed afterwards by removing the air previous to the addition of the water.

If the quantity of powder is small, or it is desirable not to put it into the scale-pan, it may be at once

introduced into the bottle, and weighed in it. The only objection to the adoption of this plan in all cases is, that odd numbers are introduced into the calculation instead of the even ones, 50 or 100. In the case of such substances as iodine, which acts upon the scale-pan, or charcoal, which adheres to the neck of the bottle, or to the paper by means of which it is introduced, it is much the best plan to weigh them in the bottle, and the calculation may be made as before.

Wt. of Water.	Wt. of Charcoal.
As 44.5 grs.	: 58.25 grs.

In case the powder to be examined was a salt soluble in water, spirit might be substituted, and the specific gravity calculated from it. If both water and spirit were objectionable, oil of turpentine might be used; but the same difficulties exist in finding the specific gravity of crystals in the ordinary way, and it is therefore scarcely necessary to allude to them. In many instances, even of soluble powders, these precautions may be safely dispensed with; for if the air is exhausted previous to the addition of the water, the time occupied in accurately filling the bottle

A quantity of powdered charcoal was put into the bottle, and was found to weigh 58.25 grains. It was then put under the receiver of the air-pump and exhausted. Water was added to fill the bottle, and it was again placed under the receiver, when a few small bubbles of air escaped. It now weighed 513.75 grains; and there were, therefore, 455.5 grains of water; and the space occupied by the powder was equal to $500 - 455.5 = 44.5$ grains of this fluid. Then,

Sp. gr. of Water.	Sp. gr. of Charcoal.
: : 1 :	1.3

is so short that no amount of solution would take place which could cause much error in the experiment. When the bottle was once filled, the subsequent solution of the salt would be of no consequence, as the object has been attained of finding the quantity of water required to fill the bottle, and, thereby, the space occupied by the powder.—I am, sir,

Your obedient servant,

J. BIRKBECK NEVINS, M.B. Lond.

ANALYSES AND NOTICES OF BOOKS.

“L'auteur se tue à allonger ce que le lecteur se tue à abréger.”—D'ALEMBERT.

Principles of Forensic Medicine. By WM. A. GUY, M.B. Cantab. Parts 1, 2, 3. 12mo.

It is not very long—a few months—since we noticed the two first parts of this work. Part the Third has just been published, and our critical duties admonish us that we should say a few words on its appearance. Dr. Guy's position as professor in one of our largest and most flourishing medical educational establishments seems to require so much from us; and then, having dipped into the work, we became strangely possessed with the idea that we had already read the book; every illustration seemed as familiar to us as the face of an old friend; the very turn of the language and phrases employed,—and who that writes has not his own peculiar style?—struck familiarly on our eye; and when we tried them aloud, they still fell as well-known accents on our ear. “We have

read all this before,” we exclaimed; but that is impossible; the book is but just out; published by Mr. Renshaw, and sent, parts one, two, three, to the Editor of the Medical Gazette, with the publisher's compliments. The book was old and it was new; it was familiar, yet it came in the guise of a stranger. We were not long of finding a solution of the riddle. Our attentive readers will recollect that we gave a brief notice—brief in contrast with its very ample and unusual merits—of Mr. Taylor's Manual of Medical Jurisprudence, some three or four weeks back: we spoke of it as “one of the very best books of any description we had ever read;” and so it is;—and having displayed it before us on the right hand, and in like manner displayed Dr. Guy's “PRINCIPLES” on the left, we began to con the two books paragraph by paragraph, page by page, and we said to ourself straightway—“An apple cleft in two, is not more twin: one face, one voice, one habit, and two persons—a natural perspective, that is and is not!” Who should unravel us the mystery? We remembered Mr. Taylor deeply versed in

medico-legal lore when Dr. Guy could have been little more than a school-boy—nothing more than the medical student, certainly—and we never for one moment imagined that he could have been borrowing from Dr. Guy. Had Dr. Guy been a pupil of Mr. Taylor's however, taken copious notes of his teacher's lectures, become a professor of forensic medicine on the strength of what he had learned at Guy's Hospital, and then committed the grave error of mistaking Mr. Taylor's views and information for his own, the whole difficulty would be cleared away; and having made inquiry, and been informed, that Dr. Guy had actually been a pupil at Guy's Hospital, and having further recalled to mind a short paper of Dr. Guy's, published some two or three years back, upon "the best method of keeping a common-place book," we began to see how the Professor had truly—we must imagine in all innocence—been guilty of publishing his notes of Mr. Taylor's lectures, and his extracts from Mr. Taylor's Manual, as his own Principles of Forensic Medicine. "Take your notes and extracts," says Dr. Guy, "upon separate leaves of paper, arrange them under their appropriate heads, and when you want the materials for a lecture you have but to undo the string, and, *presto!* without more ado than by help of an *and*, and a *but*, and a *however*, you have a lecture ready." The same receipt will answer for the manufacture of a book; and we feel reluctantly bound to say that Dr. Guy has followed it to the letter: the third part of his "Principles," with which we have

Taylor (p. 21),

and from

Guy (p. 401.)

"Habit, it is well known, diminishes the effect of certain poisons: thus it is that opium, when frequently taken, loses its effect after a time, and requires to be administered in a much larger dose; indeed, continued opium eaters have been enabled to take at once a quantity of the drug which would have infallibly killed them had they commenced with it in the first instance. Dr. Christison has remarked, that this influence of habit is chiefly confined to poisons derived from the organic kingdom, and I quite agree with him in thinking that the stories related of arsenic eaters, and corrosive sublimate eaters, are not to be credited. * * * As a general principle we must admit, that habit cannot altogether counteract these insidious effects of poisons, but that the practice of taking them is liable to give rise to disease, or to impair the constitution."

more particularly to do at present, is beyond all question entirely concocted from his notes and extracts from Mr. Taylor's Manual, taken on separate slips of paper, with some few interpolations from Dr. Christison's work on Poisons.

In such a subject as medical jurisprudence great latitude in seeking information from others is of course allowable—nay, is indispensable; and this we find and admire in Mr. Taylor: his references are incessant, and having, along with those who have laboured at the MEDICAL GAZETTE, still striven to make its pages *permanent records of experience in medicine*, we are flattered in seeing how largely they have contributed to aid so able a critic and so accomplished a writer as Mr. Taylor; but he who uses information of this kind must take it at the source—not at second-hand; he must bring the disciplined mind to digest and use it aright, to show it in its relations with every other part or pendant of the subject. Faust's receipt, which we quote for Dr. Guy's especial benefit, as we see he refers to one German book at least, will not answer:

"Sitzt ihr nur immer! leimt zusammen;
Braut ein Ragout von anderer Schmaus,
Und bläst die kümmerlichen Flammen
Aus euren Aschenhäufchen 'traus!"

Which being interpreted, means that it will not do to make paste and scissors do all; or, pretending to boil a pot of your own, to fill it not only from other folks' stores, but to boil it with other folks' fire.

We give but a single instance of parallel passages from—

"*Habit*.—This has the effect of diminishing the influence of poisons derived from the vegetable kingdom, but of increasing that of mineral poisons. Thus while opium, alcohol, and tobacco, lose their effect by repetition, and may be taken at length in doses which would poison a man not accustomed to their use, arsenic, and the preparations of mercury, produce more effect the longer they are taken. * * * It must be borne in mind, however, that even those substances, to the action of which the system most easily adapts itself, produce permanently injurious effects on the system."

This, to the critical reader, will suffice—it is Taylor condensed and abridged; it is Taylor done into Guy. But it would be easy for us to show much more, and even more remarkable appropriations; information that is singular in Mr. Taylor's Manual set down as if it were familiar and common in the Principles; points that belong to the Manual in peculiar, misapprehended and set down amiss in the Principles; as where Dr. Guy says (page 456) that by applying heat to the dry arsenite of copper we procure a ring of *metal*: it is arsenious acid that is sublimed, and the experiment is Mr. Taylor's own, and was devised as a means of verifying the nature of the green precipitate of copper; even defects or errors in the Manual are copied into the Principles, as where the quantitative analysis of sulphuret of lead (p. 943) is given, 100 parts = $86\frac{1}{2}$ metallic lead, and Dr. Guy says "the corresponding quantity of the several salts may be ascertained by simple calculation." But we defy him to do any thing of the kind; and the question in a case of poisoning is never as to the quantity of metallic lead in a salt, but as to the quantity of the poisonous salt that has been administered, judging from the quantity discovered in matters vomited, or found in the contents of the stomach after death, and which is to be ascertained in the readiest way by converting that salt into a sulphuret, as stated by Mr. Taylor, who could only have meant thereby to obtain a standard by which to estimate the quantity of the poisonous salt of lead which had been swallowed: such and such a proportion of this salt, corresponding with 100 of the sulphuret. The deficiency in the Manual, however, is not corrected in the Principles—it is left a blank, save to the far-advanced reader, as it is in the Manual.

To conclude, we refer Dr. Guy first to a passage in Marx's *Aecsius*, published in last week's *GAZETTE* (p. 185), where he says: "The *intaglio* of the accomplished observer and collector is often used by the ready penman for making a cast from *relief*. His business is to make his work as much like a foundling hospital as possible, where the parentage of no individual can be known; nevertheless it very commonly shows like an orphan asylum in the

end,—it still bears unquestionable evidence, at all events, of the poverty of its immediate origin."

If Dr. Guy can lay his hand on his heart, and say that he has not used Mr. Taylor's *intaglio* to make a cast from *relief*, calling the copy his own original work—that he has used no effort to disguise the parentage of his matter, arrangement, and conclusions—but that having heard Mr. Taylor's lectures long ago, and diligently taken notes—having also read Mr. Taylor's manual carefully, and made copious notes and extracts therefrom—having put these several notes and extracts up for some short time within the boards of his common-place book, to undergo concoction and maturation, and then taken them down, strung them together in a semi-vacuous or wholly oblivious state of mind as to the sources whence they were derived, and published the *refaciamento* as his "*Principles*,"—we shall try to find an excuse for him, and even do all in our power to help him out of the dilemma in which he has unwittingly placed himself. If he cannot do all this, let him immediately recall the bastard which he has christened and sent into the world with his name. The miserable urchin who picks a pocket to the value of a shilling is sent to Bridewell for six weeks for the deed: shall there be no moral tribunal to adjudge in cases of larceny of a kind no less disgraceful than pocket-picking, though they may not perchance be cognizable before the magistrate, nor to be estimated in the current coin of the realm? We cite Dr. Guy before our tribunal, and require him to purge himself of the moral delinquency with which we charge him,—the appropriation of another man's labours, not only without due acknowledgment,—which would not yet excuse the misdeed, but with a studied purpose to conceal the theft.

MEDICAL GAZETTE.

Friday, November 15, 1844.

"Licet omnibus, licet etiam mihi, dignitatem
Artis Medicæ tueri; potestas motio veniendi in
 publicum sit, dicendi periculum non recuso."

CICERO.

THE DILEMMA, AND REMEDY
THE FIRST.

ASSOCIATION OF THE GENERAL PRACTI-
 TIONERS WITH THE ROYAL COLLEGE OF
 PHYSICIANS.

THE great body of the profession are cut off from the stock to which they clung with a kind of insensate partiality, like the pliant vine to the sturdier elm, in classical language or allusion. The Council of the Royal College of Surgeons have utterly rejected 11,700 of the 12,000 members of the College; that is, they have rejected 39 in every 40 of the gentlemen who all entered on the same grounds of qualification, and after having had their competency tested by the same process of examination. Will the members of the Royal College of Surgeons sit down contentedly under this? If they do, it is their business, not ours; but if they do, let them write themselves worthy of the unworthy usage they have received. As members of the College of Surgeons we have done with them; but we have still a duty to perform to the MEDICAL PROFESSION, and through this to the public. We are Quixotic enough to love and admire the medical profession apart from the lucre of the thing, and the fees it brings as means of present existence; we would ennoble it, and fain hold every even its humblest member as a mortal made of a kind of better clay; he ought to be so at all events; and it seems to us to be the sacred duty of all who feel a spark of the fire divine within their breasts, to strive to make him so. The College of Surgeons reject their members who are also licentiates of the Apothecaries'

Society. They desire to constitute themselves a College of pure surgeons. Be it so: we do not object. But we do not think it advisable that the general practitioners should imitate the example thus set, and associate themselves into a separate College; and this for very sufficient reasons, which we shall give more at leisure; we see no necessity for the step; we have Colleges enow already; and then we see a provision in the acts and statutes of the Royal College of Physicians, which, did that old and most respectable body see fit, might be made to meet the present exigency, and would provide for the future standing, and, we venture to add, increased respectability, of the general profession of medicine in England.

"The College of Physicians," says Dr. Davies*, "has invariably guarded the rights of its members to practise surgery, from the 32d Henry VIII. down to the present time. As the law stands, a physician, if belonging to the College of Physicians, may practise surgery in any part of England." "And forasmuch," says the act referred to above, "as the science of physic doth comprehend, include, and contain a knowledge of surgery, as a special member and part of the same, therefore be it enacted, that any of the said company or fellowship of physicians, &c. may practise and exercise the said science of physic in all and every of its members and parts, any act, statute, or provision made to the contrary, notwithstanding." This is quite sufficient: Wherefore should not the Royal College of Physicians proclaim itself ready to open its doors to every gentleman, a general practitioner, who has complied with the regulations of the two corporate bodies whose examination he has successfully undergone? There is the very title

* Exposition of the Laws that regulate the Medical Profession.

ready made at the College of Physicians for general practitioners—*Licentiates*—from among whom any higher grade that the College might still be disposed to retain might be recruited.—There have been distinguished Fellows of the Royal College of Physicians before now, who were first Apothecaries and then Licentiates. The present order of Licentiates of the College, who are all graduates in medicine, and have for the major part complied with regulations in regard to education, hospital attendance, and length of study, of sufficient stringency, might be raised to the honour of the Fellowship at once, and the new Licentiates substituted in their stead. Nor would we have any invidious distinction drawn between these gentlemen and any who may enter in conformity with any prospective regulations which the College of Physicians might see fit to make in reference to the admission of future Licentiates.

The way in which the affairs of the College of Physicians have for several years past been administered, have given the greatest satisfaction to all who have been connected with the body: invidious distinctions, based on the University where a man chanced to have taken his degree, but could not have obtained his medical education, have been abandoned: he who laboured diligently at his profession, and maintained his private honour unsullied, was sure to be noticed, and in due season to be selected for the fellowship. There has been no heartburning or quarrelling between the College of Physicians and its licentiates or members for many years past, nor need there be anything of the kind again.

This plan of uniting the great body of the profession of medicine under shelter of the most venerable, most learned, and despite of everything that may be said to the contrary, most re-

spectable of all the divisions or conventional designations of a profession that is truly one and indivisible, appears to us fraught with even greater prospective than present advantages. It is only in this country that medicine is held in less esteem than surgery. Did we grant that surgery is perhaps generally more interesting to the individual than medicine; we should still maintain that medicine, allied with its liberal studies, is vastly more important to the mass: he who has a gangrened leg requires the surgeon to take it off, and would be lost were there not the friendly steel at hand; but endemic disease, and epidemic or pestilential disease, walk over the land, and bring the lives of thousands at once into jeopardy, and medicine steps in, investigates the causes of the distemperature, and, mitigating or annulling these, not only adds years to the sum of each individual human life, but gives a Jenner to the world, and secures life to thousands who would have lost it on the threshold of existence, and as yet unconscious of its sweets.

Could we imagine that the turmoil that has occurred, and the anxiety that has possessed the professional mind for the last few months, would lead to such a consummation as this, we should indeed think that all had been well endured.

The mode of effecting the union suggested we leave, as of easy application: almost the only point that the College would require would be that the licentiate gave up all external vulgar insignia of his calling, such as red lamps, &c., and put away every appearance of shop and trade; he, on his part, would stipulate for liberty to furnish his own patients with the medicines which he himself thought necessary. Twenty years would not go by till that occurred in London, and all the large towns of England, which has

already taken place in Edinburgh, Glasgow, &c., viz. that no professional man would keep medicines in his house, save for cases of emergency in the night, but would write his prescription, which would go to the chemist, who would be strictly prohibited from interfering with medical practice.

The plan suggested would have this farther advantage—it would not be opposed by those who have been prime movers in the construction of the Medical Bill. We threw it out to the distinguished individual who has the credit or discredit, according to different men's views, of the projected Bill, and his reply was: "Let the College of Physicians take them and welcome,"—meaning the general practitioners. The general practitioner ought never to have been separated from the College of Physicians: his being so at the time the Act of 1815 was passed, was a grave error. Had the College had this respectable body of men for its licentiates,—and it might have had them, would it only have yielded a single point that has virtually been conceded since,—and wishing to retain the class of Fellows, made the degree in medicine the simple ground of primary distinction, it might now have been powerful by its wealth, and influential by its libraries and museums, as it is only powerful in virtue of its good name, but helpless to further the art and science of medicine, by any of the great means and appliances to that end.

THE MEDICAL PROFESSION BILL, No. X.

ONE of the clauses which has been held among the most important in the proposed bill, is the 26th, which refers to the REGISTRATION of medical practitioners. This clause enacts, that no person who is not registered by the Council of Health and Education, shall

be appointed to any medical or surgical office in any hospital, prison, workhouse, &c., nor in her Majesty's Army or Navy, nor in the service of the Hon. East India Company (unless he be a native of India); and it gives the Council of Health and Education power from time to time to make regulations for specifying what institutions are to be considered public institutions within the meaning of the Act; and which form of testimonial shall be necessary to qualify the holder for every such situation.

No doubt appears to be entertained by the profession generally of the advantages of every part of this clause, except the last. It does not, however, secure much more than has been long sanctioned by usage: the governors of public institutions have insisted for many years, even on candidates for their medical offices having a legal qualification—a license from the Apothecaries' Society at least, frequently a diploma from a Royal College of Surgeons; and, with reference to physicians, a degree from some accredited University, and, in many cases, a license from the Royal College of Physicians in addition.—And then, as to the Army, it is quite certain that no man has been appointed in the medical department during the last half century and more, who had not had a diploma from the Royal College of Surgeons of London, Edinburgh, or Dublin. The Navy may have been more lax; but the present Physician-General has long discouraged applications for admission on the old certificate of competency to serve as surgeon's mate; and no man among assistants has for many years been promoted to a higher grade, who had not the diploma of surgeon from one of the Royal Colleges. The same rule has also, we believe, been long acted upon by the Board of Directors of the Hon. East

India Company. There would, nevertheless, be great advantage in a general list of registered, *i. e.* legally qualified medical men, published by authority. The Army and the Navy, and the Law, have their lists severally; and the time has certainly now come when we ought to have our MEDICAL LIST also. At more than one of the meetings of medical men held throughout the country, it has been noticed as a defect in the 26th clause, that the purposed registration is not imperative. We do not see, however, how anything having reference to the individual only can be made imperative in such a country as England, even as regards medical men, who certainly, whatever their other virtues,—and all our readers know that we estimate them very highly,—are still no Hampdens. We do not think it would do to compel them to register. They have motive enough in the 27th clause of the Bill alone.

The part of the clause that has naturally excited suspicion, is that which gives to the Council of Health and Education the power of specifying both the institutions that are to be considered public, and the title of the testimonial that is to qualify its holder to fill their medical offices. Suppose the Council of Health and Education to say that every paltry dispensary should be held a public institution, and that its medical officers should be associates of the College of Physicians, or Fellows of the College of Surgeons, it is obvious that there is nothing to prevent them from doing so, and thereby excluding the Licentiate in medicine and surgery from everything like public professional position. This is one of the insidious elements, as they have been characterized, of the bill; it is the drop of venom infused into the quart of wholesome drink; apt to be taken without suspicion, only to be discovered afterwards to be deadly.

The 27th clause enacts, that persons registered by the Council of Health as physicians, surgeons, or licentiates, shall be exempt, while practising as such, from being summoned on juries and inquests, and from being required to serve corporate, parochial, ward, hundred, and township offices; it farther declares, that the certificate of no unregistered person shall be received as the certificate of a medical or surgical practitioner in any court of law, or in any case in which such a certificate is required.

This clause cannot, we believe, be viewed as conferring any privilege that is not already accorded us, either by law or usage, which last, in England, is very commonly held of the force and avail of law. Still, as it confirms and makes statute-law of privileges that are absolutely indispensable to the existence of the practitioner of medicine, it must be viewed as right and proper. We rather think the medical profession have another privilege than any that is here accorded—that of being exempt from serving in the militia. But upon this point we are not quite certain; and were it as we rather think it is, the privilege is indefensible, and should be given up. All and sundry, gentle and simple, must be ready to serve as a militia-man, in case of danger or emergency to the country. Were the cry again to be: "*Pro aris et focis!*" we of the medical profession would surely never be found lagging in the rear.

Clause 28th provides for the registration of persons now practising. The Council are to have the power, during the next twelve months after the passing of the act, on application made, to register every person legally practising as physician, surgeon, or apothecary, on the production to the Council of his diploma, license, or certificate, or of such other proof as shall be satisfactory

to the Council. For persons abroad, the time of registration is extended to two years. Fellows or associates of any of the Royal Colleges of Physicians or Surgeons are to pay a fee of £2. on registering; in every other case the fee is to be five shillings. The fees are to be applied towards the expenses of the Act.

Now I am a member of the Royal College of Surgeons; I have practised as a surgeon for twenty years or more, prescribing for my patients, they having had my prescriptions made up at a chemist's—I have practised as a *pure* surgeon. But I have had no particular friend a member of the Council of the Royal College of Surgeons, and my name neither appears in the first nor second batch of Fellows, though there are men there who were my dressers or apprentices. What is to become of me? shall I be admitted to register as a surgeon—my grade, or must I descend to the licentiates? They are only Fellows of Royal Colleges who are provided for; he who is a pure surgeon, yet no fellow, is left out of consideration, and as a correspondent of last week said, may “take to the coal or wine trade,” unless he consents to eat humble pie, present himself for examination, pay another fee, and take his place at the bottom of the list.

In a number some time back, we made a grave mistake in regard to the amount of the registration fee for persons already engaged in practice. Clause 13th enacts definitively, and without reference to any ulterior proviso, that “a Register shall be kept and published from time to time of all persons who shall have been examined, and shall exhibit before the said Council letters testimonial of their qualification to practise as a physician, or as a surgeon, or as a licentiate in medicine and surgery; for which registry the Council shall be entitled to have from

the person requiring to be registered, a fee of £5, in the case of a physician or surgeon, and a fee of £2, in the case of a licentiate.” This, we now know, refers to those who may enter the profession subsequently to the passing of the Act; those who are already engaged in practice are to pay fees of £2, and five shillings.—From the returns of the occupations of all persons in these countries, it may be assumed that the number who would claim registration as medical practitioners may be about 20,000, of whom one-tenth, or 2,000, may practise as physicians or pure surgeons, and 18,000 as general practitioners. The sum levied on the physicians and surgeons would therefore amount to £4,000, that on the general practitioners to £4,500. This is not nearly so large a sum as we descended on formerly; and it is probably still too large. But, on the whole, it would probably not be going too far to say, that a fine of from £6,000 to £8,000 would be levied on the members of the medical profession domiciled in these countries, if this clause were suffered to stand unmodified, and the Bill became law.

We ask our brethren if their incomes are so large that they will suffer the minister to put his hand into their pockets, and take from them this amount without complaint? at the same time, be it observed, that they are told they are not fit to be trusted with a voice in the management of their own corporate affairs, though they may be good enough to spread a plaster and administer a clyster.

MOVEMENT IN THE PROFESSION.

THE Council of the Glasgow Medical Association have made what we cannot but regard as a very good report on the Medical Bill, and coming from gentlemen living under another state of things from ourselves, and unbiassed, *uninterested*, save in so far as they are

medical men, we beg to call the attention of all whom it may concern to this able document. It is too long for us to reprint, but the Hon. Secretary, Dr. Maclear, 12, George Street, Glasgow, we doubt not will forward it, at the cost of the postage, to any one who applies. The Glasgow Association we may say generally, approves of the institution of a Council of Health and Education, but would have no member of it appointed by any of the Royal Colleges; they would have nine members appointed by the Crown, and nine by all enregistered physicians, surgeons, and general practitioners: two by those of Scotland, three by those of Ireland, and four by those of England. The Glasgow Association say justly of the bill that:—

“Dividing the present Incorporated Practitioners into the two classes of Physicians and Surgeons, the Bill continues them in all their several corporations, as Universities and Colleges—selects them alone from the whole profession for supplying men to form nearly two-thirds of the Council—upholds and enhances their exclusive privileges in medical teaching and medical licensing; and, in fact, is so much occupied about them alone, as to be little else than a new code of rules for guiding them in the exercise of their privileges, and in their new relation to the Council. Maintaining the present division of medical men into Incorporated and Unincorporated Practitioners, and constituting the latter into a third and separate class, under the new name of Licentiates in Medicine and Surgery, the Bill not only does not admit these Licentiates into any of the class privileges of the Physicians and Surgeons, but does not convey to them any one privilege as a class: it just continues them what they now are, viz.—a mere crowd of individual citizens, who, in their profession, are devoid of legal government, of legal union, of political status, and of political privileges; and, despite of their numerous and repeated applications as Medical Reformers, and although they form nineteen-twentieths of the medical profession within the three kingdoms, it is truly for them a Non-Medical Reform Bill.”

The Council of the Glasgow Association would propose these amendments on the bill:—*first*, that all unqualified persons who shall practise any of the branches of the medical profession for *fee or reward*, should be liable to prosecution, by some public prosecutor, (or by some summary pro-

cess); *second*, that the constitution of the Council should be such as we have stated; and—

“*Third*, that all existing Unincorporated Practitioners be constituted into a new corporate body, under some such designation as “The Imperial Medical College;” that, after the passing of the Bill, all enregistered persons, not associates or fellows of the existing Colleges, nor Professors in the Universities, become members of this New College in virtue of their registration; that its offices and laws be in accordance with the free nature of its constitution, as well as with the general regulations of the Council; that all its members be co-equally electors for, and co-equally eligible to, its offices; that its members be recognisable as legal teachers of the medical sciences; and that, whether the licensing powers of the Apothecary Company be or be not transferred to it, it be a licensing body on a par with the licensing bodies mentioned in the Bill.”

In conclusion they say,—“Should the First Amendment be adopted, but not the two last, the Bill will be improved; but, as unincorporated practitioners, we shall be so little benefited by it, that we will be under the obligation of continuing to advocate and urge Medical Reform; should the Second be also adopted, but not the Third, the same obligation will lie upon us, although the constitution of the Council would be exceedingly liberalized. But should the Third be also adopted, Medical Reform would substantially be carried. And our conviction of this is the reason why we have said that the Bill, viewed as a code of rules for the incorporated bodies, is quite compatible with Medical Reform.”

The profession of York met at the Dispensary on the 26th inst., Dr. Goldie in the chair, and passed the usual resolutions of thankfulness to the minister for introducing a Bill, and for the opportunity afforded the profession of discussing the measure; approving the institution of a Council of Health and Education, but expressing an opinion “that the general practitioner should be fully represented in it;” that the body of general practitioners should take part in the examination of the practitioners of their own grade, and that for this purpose they should be incorporated in each division of the United Kingdom; that measures of easy application to prevent unqualified persons from practising are required, &c.

A meeting of the medical men of

Chichester and vicinity, was held at the Chichester Infirmary, on the 31st ultimo, and expressed satisfaction with the introduction of the Bill; with the maintenance of the existing distribution of the profession of medicine into physicians, surgeons, and general practitioners; they thought, however, that the constitution of the proposed Council of Health ought to be such as will represent each grade of the profession effectively; and that it would be highly detrimental to the public health, were all restrictions, as proposed by the bill, to be removed from the practice of medicine in each and all of its branches.

The practitioners of Bath met on the 5th instant, Mr. Norman in the chair, and passed resolutions generally favourable to the Bill. Mr. Soden made an excellent observation in proposing the first resolution (which was merely expressive of gratitude to the Government for having thought the profession worthy of legislative enactment), to the effect "that the proposed Council of Education and Health would have the power of materially improving the profession, if they would institute an examination of medical students preparatory to their registration as such, with a view of ascertaining whether they had received a good sound general education previous to the commencement of their professional studies." Alas! there is no provision for any thing half so advantageous to the profession, and the Council could never do anything nearly so likely to be beneficial.

The second resolution thought that the nomination of six members of the proposed Council of Health by the Government was too many, and that the proceedings of the Council ought to be open to registered practitioners at all reasonable times.

The third approved of the system of registration, and

The fourth deprecated the repeal of the Apothecaries' and all other Acts, without substituting some more enlarged measure of protection to the profession and the public.

The Bath practitioners appear to us to be in the same predicament as the Colchester folks; they approve of the Bill in their orations, and then quarrel with every one of its provisions, and with some of its essential principles, in their resolutions.

The practitioners of Manchester held a meeting, numerous attended, on the 6th instant, Dr. Bardsley, sen., in the chair. The first resolution was the same as that at the other meetings noticed in this day's Gazette, but expressing "surprise and regret" that, whilst all the protective enactments were swept away, no new and more efficient one had been substituted. The second resolution approved of a general Council, but not of one with the constitution of that which is proposed. The third resolution was expressly condemnatory of the proposition to remove all restriction on unqualified practitioners. A petition was agreed on in conformity with the views of the speakers, and the resolutions passed.

This meeting appears to have been conducted in the best taste and temper. Every one was listened to patiently; several amendments were proposed, calmly discussed, and disposed of. Altogether it was characterized by the good sense and love of fair play which we have ever admitted in our friends of Manchester.

THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

On Tuesday evening last the first meeting of this Society for the season was held at its house in Berners Street, Mr. Stanley in the chair. On assuming his seat the President took occasion to advert to the prospects of the Society, which he spoke of as flourishing. In point of entertainment the present promised to be as brilliant as the last, or any preceding session of the Society. He congratulated the Fellows on having met once more for the cultivation of good understanding, and for their mutual improvement.

Papers were communicated on a Disease of the Gall Bladder, by Dr. Roberts; on an Obstruction of the Vena Cava Ascendens, by Dr. Peacock, of Edinburgh; and on the Natural History, Anatomy, and Physiology, of the *Echinococcus Hominis*,—an abstract of which, with a report of the discussion that followed, will appear in our next.

DEARTH OF SUBJECTS FOR DISSECTION.

We are sorry to hear complaints from all quarters of the scarcity of bodies for the dissecting-room. At University

College and King's College they are all but at a stand-still through the deficiency. The destructive influences of idleness on the minds and morals of students cannot be estimated too highly. These young men are actually roaming about the streets, and appear to be getting into mischief because they cannot find occupation in the legitimate business of their studies. The Home Secretary must look to this state of affairs immediately.

INCORPORATION OF GENERAL PRACTITIONERS, AND THE MEDICAL BILL.

To the Editor of the Medical Gazette.

SIR,

I HAVE not yet seen two pamphlets addressed to the general practitioners, the one by the Society of Apothecaries, and the other by the practitioners of Marylebone, so that I am not aware what measures are most recently recommended for the adoption of that body in the present important crisis. Your next number will be in print before I can receive these publications, and I am unwilling to defer for another week a few remarks on the present position of the general practitioners, in relation to what I conceive that would be under Sir James Graham's Bill. Though I am a decided advocate for the Bill, amended and modified, as I trust it will be, and equally so for the repeal of the Apothecaries' Act, when that can be done with justice, I must confess that I think the position of the general practitioner under the bill as it at present stands will be worse, as regards material interests, than it is at present. But even as it at present stands, the bill is, I conceive, calculated to elevate the character and position of the profession as a whole. The entire tendency of the measure is to harmonize, unite, and consolidate the existing *membra disjecta* of the profession in the three kingdoms, and its most prominent defect consists in its failing to do this to a sufficient extent. In addition to these merits it possesses the pre-eminent one of placing the profession in an honourable position in relation to the state. The advantages, however, are only indirectly and remotely afforded to the general practitioner, but will, as the bill at present stands, be almost exclusively enjoyed by the physician and surgeon. Again, whilst in the case of the higher walks of the profession these are hardly likely to be affected by the working of the bill, the material interests of the general practitioner are but too likely to suffer. Positive protection under the Apothecaries' Act, or at least

the name and semblance of such, he will exchange for mere negative discouragement and registration.*

On the other hand, the licentiate in medicine and surgery will exchange the (in this country) obsolete, and (as applied to a practitioner of medicine) anomalous designation of apothecary, for one in every way more befitting him, and calculated to raise him in the estimation of the public. This is as it should be; but I can hardly avoid expressing the hope that, in connection with this, the Society of Apothecaries will voluntarily retire from all participation in the examination of future licentiates (a duty which though they have most ably performed should never have devolved upon them), and return to their original and really honourable position of a guild or municipal corporation. Justice, however, the interests of the general practitioner and of the community, and, I will add, the interests also, when viewed correctly, of the entire profession, all require that the body of general practitioners should be adequately represented in the Council of Health and Medical Education, and that they should likewise be brought into fitting and honourable relations with the Colleges of Physicians and Surgeons. Unless these two points, and direct protection in some shape, be gained, although I should still regard the bill as a boon not to be rejected, making, as it appears to me, so many steps in the right direction, a great amount of good will still fail to have been obtained. It will, I trust, be admitted, that all classes of the profession should unite in endeavouring to procure such alterations in the bill, as will, so far as is possible, ensure the dignity, order, and harmony of the profession, both as a whole, and in its several parts. Now as the profession is at present constituted, and as it is proposed, and I think rightly, that it should be constituted under this bill, I do not see how these objects are to be attained, without the licentiates in medicine and surgery, at least in England, (constituting, as in that part of the United Kingdom they do, a great third estate of the profession,) being at once formed into a Society, by a Royal Charter of Incorporation. This Society, or College, should, under the provisions of the bill, elect from two to four members of the Council of Health

* Chemists and druggists are the class against whom the public and profession will have most serious need of protection. All respectable pharmacists, however, are opposed to all medical practice, unless of the very simplest description at the counter. This can never be entirely suppressed. The Pharmaceutical Society will probably co-operate in endeavouring to procure a prohibitory clause against chemists and druggists acting as medical practitioners; this being contrary to the fundamental rules of the Society. If this were done, and the laws against mal-praxis by the unqualified made more stringent, all perhaps would be done that the state can effect.

and Medical Education; should either alone, or, as is more in unison with the provisions of the present bill, (and as I think is to be preferred,) in co-operation with the Colleges of Physicians and Surgeons, conduct the examination of the Licentiates in Medicine and Surgery; and should frame bye-laws for maintaining the orderly and honourable practice of the profession, by its members, both in their relations to the public, to each other, and to the other grades of the profession. These bye-laws, like those of the Colleges of Physicians and Surgeons, should be subject to the approval of the Council of Health and Medical Education.

Without going further into details, I will briefly add, that I should rejoice to see the metropolitan and provincial general practitioners, supported by their brother practitioners of the higher grades, (for I suppose we must retain the name,) at once, and with one voice, memorializing the Queen, through Sir Graham, for the grant of a Charter of Incorporation. When that which was so recently granted to the Pharmaceutical Society is remembered, a charter can hardly with any shew of reason, or of justice, be refused to so important and generally meritorious a body as the general practitioners. Let them only ask for what is just and reasonable; let them but submit to have the foundation of their edifice laid one step lower than those of the Colleges of Physicians and Surgeons, and not aim at exact equality with these bodies, and I cannot see why the latter should oppose, or rather, why they should not promote, so expedient, and, as I would submit, so just a measure, as the incorporation of the general practitioners.

In conclusion, I would express a hope that at the ensuing meeting at Derby, the interests of the profession as a whole may be fully, cautiously, and dispassionately considered; and then we can hardly doubt that great good will result from the meeting.—Allow me, sir, to subscribe myself,

MEDICUS.

November, 1844.

THE MARYLEBONE MANIFESTO.

To the Editor of the Medical Gazette.

SIR,

I AM certain, from my personal knowledge of many of the members of the Marylebone Association, that you have rightly interpreted their feelings in your last week's commentary on the "Manifesto" just issued. This document is perhaps the most important that has met the public eye since Sir Graham's Bill was introduced into Parliament; so, at least, it appears to me, and

so it is evidently regarded by you. Many of the names attached to it are those of gentlemen past the meridian of life, whose fortunes may be said to be made, and who cannot be reached by the imputation of motives of pecuniary gain, or selfish ambition. And these are the individuals, who, if report speak truly, are the most zealous in this new movement. What, then, but a sense of obligation to fulfil a public duty, has dictated the course they have taken? The Marylebone Manifesto gives a clear insight into the deep interest which the people of these realms have in the laws affecting the general practice of medicine. It very properly treats the question affecting medical distinctions as of subordinate importance. Although its clauses apply to the "Medical Reform Bill" more especially, yet its arguments derive their origin from the conduct of the Council of Surgeons. It is the Council that has attempted to establish a parchment distinction between "Pure Surgeons," and "Surgeon," in the civic sense of the word.

The Marylebone Association have placed the absurdity of this in broad relief, without denying the justice and propriety of awarding surgical pre-eminence to those who really deserve it.

I doubt not, Mr. Editor, that if the College could be brought to comprehend the great mistake it has made, and to consent that its new charter should "live a day and die," it would be easy to procure a substitute, and, if conceived in a just and liberal spirit, its principles being carried out fairly, that the Association of Marylebone would appease its "anger," and a modified Reform Bill might not only be introduced into, but carried successfully and satisfactorily to nearly every party, through Parliament.

Meanwhile, your Marylebone friends must be kept up to their duty. They must promulgate their "Manifesto" in all directions. It is too strong a document to be disregarded in any quarter. "It is the truth." Let them also enrol the General Practitioners, and then, as long as they confine their objects to the *public good*—which is *the good of the profession*—they will find themselves in possession of a power irresistible against evil.

There is one point in which I presume to differ from you. I do not believe the establishment of "a College of General Practitioners" an Utopian project. On the contrary, however it may be brought about, I believe it is that which must come. What is "pure surgery?" How many men could get their living in the metropolis, even with a population of two millions, by "pure surgery?" Let any thinking man attempt a reply to these questions, and he will most assuredly arrive at the conclusion, that sur-

gery, without a knowledge of the practice of physic, is a farce, and that a College of General Practitioners of Medicine and Surgery would be fifty-fold more important to the country, than any Royal College of the "purest" Surgeons.

If it be so in fact, let the Council persist in its present course, and I am much mistaken if we shall not see something rather practical than Utopian in the project of the Marylebone Association.

AN OLD ADMIRER.

[Our friend must have mistaken us. We surely did not treat the project as Utopian. We even went so far as to say that if nothing which we thought better could be done, that then a College of General Practitioners would probably be the best project that could be adopted.—ED. GAZ.]

UNQUALIFIED ASSISTANTS AND MEDICAL PLURALITIES.

To the Editor of the Medical Gazette.

SIR,

As medical reform is at present so prominently before the profession, and seems in a fair way of receiving that attention from government and the legislature which it so much needs and merits, we may well hope that ere long "the jurisprudence of medicine" will be with us, as it has long been with our Continental neighbours, settled on grounds more or less sound and equitable. In anticipation of such adjustment, it is well for every one to call attention to whatever he may think amiss, and to suggest any remedy that may occur to him; it remains only for the majority to adopt or reject his views. The two abuses that I now wish to urge upon the notice of all, have hitherto passed—the one nearly, and the other altogether—unnoticed, so far as I have observed, in our various meetings and written effusions. The first has been briefly, but pointedly, referred to by Mr. Carter (now of Hadley) the ex-secretary of the North of England Association, in a most able review of the proposed measure of Sir J. Graham, addressed in the form of a letter to his successor in office, Dr. Charlton, and which the Association has printed for circulation, as it so fairly represents the opinions generally held throughout this district on the subjects treated of. The abuse alluded to is the too frequent practice—in some cases the cool determination—of duly qualified practitioners to employ *unqualified assistants* (often mere lads, who have undergone no system of training whatever) to visit and prescribe for such of their patients as they themselves either could not find time, or

had no inclination, personally to attend to—generally, or always, the poorer portion. Such a proceeding surely calls loudly for prevention; and what was, at all events, partially guarded against by "the Act of 1815," it ill becomes us not to notice the omission of in Sir James Graham's proposed bill. A check should surely be put on him who would, either from a too great desire of gain, or from, if possible, a still more detestable feeling of jealousy, seek, in this most grovelling way, to overtake more practice than one man can accomplish. To such an extent, indeed, has this abomination prevailed, that a duly qualified man finds it difficult, or even impossible, to effect an engagement wherever unqualified youths are in the field. Bad enough, in all conscience, would be the case if the reason for such a state of things were the difference of remuneration required by such ill-matured opponents! How much worse, then, is it, when we learn the reason, as it is unblushingly given us by some, to be the risk that otherwise they would run of being supplanted? A pretty reason, truly, when interests so vital are at stake! An increased chance of gain is naturally attended by a proportionate hazard of losing; it is the justly inseparable accompaniment of speculation: and he who would honourably endeavour to extend his practice beyond what any personal exertions of his own could accomplish by employing a *duly qualified* assistant, must of course make up his mind to the possibility of such a one becoming, at some future day, either his rival or his junior partner.

In a profession where ignorance is crime, where culpable inactivity, or alas, more frequently, unskillful meddling, may so readily, and in a few short minutes, effect heart-rending separations, and blast the fondest hopes, how reprehensible does such conduct appear! In even a professional point of view, how dishonourable, not merely thus to retard, for a paltry gain, the onward progress of more honourable rivals, but to shut out the praiseworthy holder of a diploma, at his very outset in life, from the legitimate exercise of his talents; but how infinitely more so, how unscrupulous and heartlessly selfish, does such a mode of "doing business" appear, when, by its adoption, we see the best interests of the public deliberately trifled with, and a wholesale traffic in human life established! Well may such men sneer at and avoid our reform associations, while thus they are engaged, in our larger towns, in the systematic training of a race of impostors more dishonest and more dangerous than quacks for the rural districts.

The second point to which I would now call attention is one of much less magnitude,

but highly deserving of notice nevertheless. How evident to every one is, or was, the evil of pluralities in the Church! And why should *medical monopolies*, or pluralities, be differently regarded? In a large provincial town, for instance, boasting of an infirmary, a fever-hospital, a dispensary, and having two or three of the latter in its immediate proximity, in fact in its environs, why should so many institutions, each requiring and possessing so many physicians, be monopolized by the same number of men—nearly the same “*corps diplomatique*” in each and all of them—when *each individual charity* could readily have its *own medical staff*? The “love of place and power” must indeed be great when thus it extends to services at best but indirectly required. Is it not enough for a man that he gain his own ends? Must he needs obstruct the path of others? Is it not sufficient that he has had the use of the ladder wherewith to climb the precipitous ascent? Must he also, for prudence sake, draw the ladder up after him? Can so many offices be as efficiently filled by one man as by a corresponding number of men? In fine, are the interests of the public and of medical science not manifestly disregarded, ay, trampled under foot, for the furtherance of selfish ends, by the adoption of so unreasonable a *system*? And if so, should the public and the profession not seek to have a veto put upon it? Truly the instructive fable of “the dog in the manger” might here be aptly enough quoted as a finale. But enough, it is hoped, has already been said to secure the attention of medical reformers to two so important yet neglected subjects as those of “unqualified assistants” and “medical pluralists,” by

Yours respectfully,

A MEMBER OF THE NORTH OF ENGLAND
ASSOCIATION.

October, 1844.

NECROSIS OF THE SCAPULA.

A LABOURER, 28 years of age, had for some time observed a swelling upon one of his shoulder-blades, which increased gradually until, in the course of from six to seven months, it had gained the size of the two fists. When he came under treatment, the cellular substance and muscles lying over the scapula had sloughed, and the scapula in its upper half was found dead. A very copious suppuration was established. Pieces of the bone were thrown off from time to time by the powers of nature, or taken away by art. By and by the only part of the scapula that remained was its lower margin, and its articular or glenoid process; the superior part, with the spine, the acromion

process, and the coracoid process, were gone. The wound now began to heal, and the patient gradually recovered. The motions of the arm were much less restricted than might have been imagined from the extensive loss of bone and muscle that had been suffered. The clavicle, detached from its connections, at its outer extremity rose and projected for a time; but the skin over its point remained healthy, and by and by, in the course of the cicatrization, it was drawn down again, very nearly into its old situation.—Dr. LAMBRECHT, *Medicinische Zeitung*, No. 14, 1844.

AMAUROSIS OCCURRING SUDDENLY.

A MILITARY man, 48 years of age, had been long accustomed to take a course of mineral waters during the summer, on account of habitual hemorrhoids, with which congestion to the head, giddiness, sparks before the eyes, and some imperfection of vision, were associated. In the summer of 1841 the patient was hindered from pursuing his usual practice, partly through business, partly through an attack of rheumatic fever, scarcely recovered from which he had to join his regiment on duty. Here all his old complaints returned; and one morning on parade his sight suddenly became so imperfect, that he could not distinguish either objects or persons at a very short distance from him, and could neither read a printed page nor writing. As this attack was referred to hemorrhoidal congestion, leeches were applied to the sacrum, a large issue was made in the left arm, and the use of one of the purgative mineral waters, to which he had been accustomed, was commenced. To the mineral water was added by and by the use of cream of tartar and sulphur. The patient had so far recovered in the course of four weeks, that he was again in a condition to read rather small print.—Dr. SUFFERT, *Medicinische Zeitung*, No. 12, 1844.

APOTHECARIES' HALL.

Gentlemen who have obtained Certificates,
Nov. 7.—G. Yates, Birmingham.—J. D. Geldard, Worthing.—E. Bishop, Heckmondwike, near Leeds.

NOTICE.—If our correspondent *gamma* will call at our Printers' on Tuesday, he will find a packet for him.

ERRATUM.—In Mr. Ure's paper in our last number, at the tenth line from the foot of page 190, for “circulation,” read “articulation.”

LECTURES ON THE NATURE AND TREATMENT OF DEFORMITIES,

*Delivered at the Bloomsbury Square
Institution.*

By R. W. TAMPLIN, F.R.C.S.E.
Surgeon to the Institution.

I HAVE now pointed out the leading deformities of the ankle-joint, but before I conclude this subject, I must draw your attention to a condition of the joint I have met with, which exists without any visible deformity, but which, nevertheless, is as serious an inconvenience to the patient as some already detailed, namely, a fixed position of the ankle-joint at right angles, occasioned by a contraction or rigidity of the whole of the muscles whose tendons surround the joint; the joint, as far as motion is concerned, appearing ankylosed. It arises from inflammation in, or in the neighbourhood of, the joint, and, as in other instances already mentioned, owes its origin to the instinctive efforts constantly in exercise by the patient to relieve himself from, or to prevent an increase of, pain; there being no disease in the nerves or muscles themselves. The position at right angles is, however, the most rare, as, generally, when disease in or about the joint is a cause of contraction, talipes equinus, or talipes equino-varus, is the result; either of these deformities appears to leave, and in fact does leave, the synovial membrane of the joint more free, and less subjected to pressure, than the position at right angles. This condition, then, although unaccompanied with deformity, is, as you must perceive, a very serious inconvenience, and occasions great lameness; as, during the act of progression, immediately the opposite extremity is carried beyond the perpendicular position of the body the patient

is thrown on the anterior extremity of the metatarsal bones, and the body becomes raised beyond the natural extent; and again, in bringing the foot thus affected forwards, the heel only touches the ground at first, and the sole of the foot falls more or less abruptly, according to the rapidity with which the patient walks. The consequence is, that constant lameness, and consequent fatigue, always result, and occasionally the foundation is laid for lateral curvature of the spine, from the increased mobility kept up in the spinal column.

A case of a gentleman, 20 years of age, occurred to me some time since. He consulted me for what he imagined to be simple contraction of the gastrocnemius, and also for lateral curvature of the spine, which, however, was slight. Upon examination, I found that it was impossible to flex the foot beyond a right angle, and recommended division of the tendon; which was assented to. I accordingly divided the tendon, and proceeded in the usual manner to flex the joint. As the flexion proceeded, the foot everted (a circumstance I pointed out to you, when speaking of talipes equinus, occasionally happened), and, upon examination, the peronei and common extensor were exceedingly rigid and tense, as also the anterior tibial tendon. I proposed and advised a division of these tendons, which was assented to. After the punctures had healed, I directed the foot should be flexed and extended alternately night and morning, and in this way succeeded in obtaining free motion, which was also accompanied with voluntary power; and the patient perfectly recovered without the aid of artificial support. The curvature of the spine was afterwards cured by means I shall have occasion to point out to you when we come to speak on that subject.

This case originated when the patient was six years old, from abscesses around the joint, but which had not affected the integrity of the joint itself, and was occasioned by the constantly maintained position, every muscle

having been directed to assist in preventing motion: and this being continued for two or three years, resulted in the condition mentioned. I have since seen three cases in younger subjects, but it is rare, and will require great caution in forming your diagnosis.

With this, gentlemen, I conclude the deformities of the feet: and you cannot have failed to observe, that each of them is, at its origin, and in its less severe form, nothing more than a permanent position of one of the natural motions of the joint, whether it is congenital or non-congenital, whether attended with paralysis or without paralysis; and this circumstance alone renders it the more unaccountable and astonishing that the attention of the profession was not earlier attracted to their true character, and that the circumstances which induced Delpech to make this great and novel experiment of remedying them upon proper scientific principles, namely, the union of the tendo-Achilles and fracture of the patella, were unobserved until so recent a period, for many opportunities must have presented themselves in the dissecting-room for the study of their morbid anatomy.

In the first deformity I drew your attention to, namely, talipes equinus, there is at its onset, and during its progress, nothing more than a greater or less extension of the joint, and this amount of extension not exceeding the natural and healthy position, which, during the varied exercise to which every human being is subjected, is constantly taking place; and even the complete elevation of the heel can also be effected voluntarily, as may be seen on the boards of the Opera, for no talipes equinus can be more complete than the extreme extension the opera-dancers are enabled to effect, and for some length of time.

In talipes varus, the next considered, there is in its simplest form but the inverted position, which can be accomplished at will by any individual; and the malposition of the bones, in severe adult cases, with the contraction of tissues, is occasioned, as I have shewn you, by the weight of the body constantly stretching certain ligaments, and in this manner adding to the original position, by more or less separating the bones from their normal articulating surfaces—at least in part, never altogether; and it is a remarkable fact, that in this, the most severe deformity in appearance, and occurring perhaps at an early period of uterine existence, the bones are forced and grow in their natural relative proportions, and with their natural healthy articulating surfaces; although, with a natural inference, a portion of those articulating surfaces have never been in actual contact; thus shewing that the *nus formativus* remains uninter-

rupted, and giving us a clue to its real character and origin.

Again, in talipes valgus, you have also the eversion which is to be accomplished by the will at pleasure. The flattening of the arches of the foot, arising also from mechanical causes and a supposed debility of the passive attachment of the bones, and the two deformities arising from the first, in combination with either of those last mentioned, can be at all times occasioned by the effort of the will.

The last, viz. talipes calcaneus, being also a flexed position, and one constantly occurring in the varied motions exercised in daily life; and yet this state of things being permanent, becomes a deformity, of course aggravated from various attendant circumstances and causes mentioned. And what deformity can we meet with greater than that which is daily witnessed in the positions assumed by itinerant mountebanks, who have been accustomed from early infancy to a stretching of almost every ligament of the body.

Having now pointed out to you the true character of the deformities of the foot, I must just draw your attention to the congenital deformities. These consist of talipes varus, talipes valgus, and talipes calcaneus. I have never met with talipes equinus. You will recollect I stated that, in my opinion, it was position, and position alone, which caused these malpositions (or rather the permanent extreme natural position, for this is its real character) during uterine existence; and if you observe the character of these three congenital deformities, I think you will have little difficulty in reconciling the possibility, if not the probability, of this being the case. Take the first mentioned, talipes varus: there are many positions in which the extremities of the child may be kept in utero, which would adapt it better to the cavity of the uterus, provided the feet were inverted; and it so happens that by far the greater number of congenital cases consist of double varus; and where it does not consist of double varus, nothing is more easy to account for than one or other extremity being so placed, that the foot should grow in that position, whilst its fellow may be free and unconfined. Then, if you refer to congenital valgus, this also may be easily imagined—that the extremities or extremity may be so situated that the flat surface of the feet press more or less on the walls of the uterus; if not constantly, sufficiently to influence the position of them during the growth of the bones and ligaments; and, be it remembered, that it is only the ligaments and muscles that we find affected, the bones retaining, in either of the three forms, their natural proportions and relative size, and it must be evident that it would not require

any force, but merely a constant position, to produce this effect,—at least it is so to my mind.

Then, again, take talipes calcaneus: this also is a position that may as easily be imagined to be constantly effected, according to the position in which the extremities lie; and if they are so situated that the anterior portion of the sole of the foot presses more or less on the walls of the uterus, of course the flexed position is the one it would assume, and that without any difficulty or resistance; as, if we suppose during the motions of the child, the position of the feet may be more or less altered as it regards the extreme amount of flexion, yet if, after these active efforts have ceased, the feet reassume this position, the gastrocnemius remaining passive, which it would do, of course the greatest amount of flexion would most easily take place, and thus become permanent, the flexors growing in the contracted condition.

The same remarks apply to each of the congenital deformities which we meet with, without malformation of the parts. I stated also to you that it was my opinion no structural shortening took place, and that there was no evidence of any morbid condition of the muscle or muscles. Now it must be remembered, that although the bones grow in an extreme position, yet, as I have before observed, they are perfectly formed, and that the articular surfaces also are in every respect perfect: so that thus far a malposition does not interfere with the *nisus formativus*. Why should it do so in the muscles or tendons? To me, the fact of the contraction of the *ciatrix* drawing together the two ends of the tendons, in the case I mentioned to you in my first lecture. The natural position of the foot being maintained, and the natural motion of the joint having been exercised by the little patient, previous to its death, is conclusive as it regards the idea of structural shortening. What evidence have we, then, of a spasmodic condition of the muscles contracted? Do they, during the exercise of volition, whether in infants or adults, present that peculiar irregular action which is so conspicuous, and, I may say, characteristic, of what we call spasm? Certainly not. The motions are as well and regularly performed in the malposition as in the natural position, so far as the contracted muscles will admit. And many cases may be seen amongst our out-patients, in whom the deformity has been removed, where the little patients exercise every motion of the foot as perfectly and with as much facility as a child who has not thus suffered. This could not be if there was that state of muscle called spasmodic, as in these cases (of a congenital spasmodic affection), of which we have had several, we know of no remedy that has success-

fully been applied; so that it does not appear there is any want of development, any diseased condition of the brain or nerves, nor any unhealthy condition of the functions of the muscles, unless the simple contraction be regarded as such. Now you must also bear in mind that the muscles which are not contracted are not in any way affected beyond their being kept constantly drawn out, and from the position of the feet or foot being constant, also prevented from contracting on themselves; but the moment the resistance is overcome you will find their power of contracting as perfect, whether in infants or adults, but more evidently in infants, as if their full amount of power had constantly been used. And you have only to walk up stairs, and you will be enabled to satisfy yourselves of this fact. So that these circumstances—I may say facts—combined, lead me to the conclusion that it is to the position that these deformities owe their origin. I have never, as I have told you, met talipes equinus congenital; I mean the simple elevation of the heel: this also confirms me in my opinion, as I cannot imagine how this deformity could be caused by position, for I can perceive no way in which the extremities of a child could be placed or formed in utero so as to keep the heel up, without any other deformity or malposition being produced. Whereas the three deformities mentioned may each of them be assumed to be placed easily in the position in which we find them.

With regard to the non-congenital deformities of the feet, you have, as I have had occasion frequently to observe, paralysis of one or more muscles, and a spasmodic affection of one or more of them; occasionally of the whole voluntary muscular system. When it is combined with paralysis, I have also stated that no known remedy has been discovered if it has been of long standing, and that we can only remove the deformity, and rest satisfied with artificial support. That the limb is always in an atrophied condition, and possesses that lifeless flabby state which is so peculiar to the paralytic condition, and as we know but little of the pathology of the nerves, I shall not waste either your time or my own by speculation or theory. Suffice it to say, that paralysis exists, and occasionally of both lower extremities, with contraction of one or more muscles, producing either of the deformities before mentioned; frequently varus of one foot, valgus, or equino valgus, of the other; the patient possessing the smallest possible amount of motion in the toes. And of course, if complete paralysis exists, you have no contraction of the knees, the limb lying in any position in which it may be placed, and appearing more like a foreign body than the living extremity, and, with the exception of the ligaments by which it is alone held, perfectly

passive; if not complete, the knees also will be found contracted, although there may be no available motion. You will occasionally find slight motion in one or other of the extensors of the leg, but not sufficient to be of the slightest use. There is always, however, as far as my present experience goes, more or less available power in the flexors and extensors of the thigh, and from this fortunate circumstance you will be enabled, after you have removed the deformity or contraction of the feet, to place the patient in a much better condition—I may say happier condition—compared to that which he has been previously obliged to endure.

About twelve months since, a patient from the country called upon me, and with great difficulty swung himself along between two crutches: his lower extremities being contracted and paralysed were perfectly

Diagram illustrating the paralytic condition of both lower extremities, which occurred in infancy from dentition. The flexors of the knees and gastrocnemii were contracted, the extensors of the knees and flexors of the feet perfectly paralysed.

useless; in fact, he could not move from the chair without assistance to raise him on his crutches. I divided the contracted muscles, and placed his feet and knees in their normal position; when, with upright supports attached to his boots, with stop-joints at the knee, he could rise from his chair, and, with the assistance of two sticks, walk; this he was enabled to do from the voluntary power he possessed in the flexors and extensors of the thighs. Since his return home he has been enabled to walk in this way about his farm, to superintend his business, whereas previously he was a complete prisoner, presenting a most miserable and pitiable appearance. The cast before you will illustrate the foregoing case most clearly.

In the case from which the cast was taken, the boy had never left his home or room except by being carried. On removing the contraction, and restoring the natural position, he also by the same means is enabled to take daily exercise with the assistance of two sticks; so that you can confer an immense amount of benefit in these apparently hopeless cases. Of course, as the deformities will consist of one or other of those I have endeavoured to explain to you, the treatment will be the same as that which is consistent with the nature of the case, and the peculiar form it may assume.

The spasmodic contractions are the most painful and difficult to treat, for although the deformity and contraction may be removed, yet we have hitherto been, and are at present, ignorant of any means of remedying the spasmodic condition of the muscles; and although by division of the tendons, and during the time the uniting medium is soft and yielding, you can easily hold the foot in any position, yet the cause exists, and the patient is unable to control his muscles. As soon as the uniting medium becomes consolidated, the same irregular action is brought into operation, and support the limb by any method you may please to adopt, you cannot remove the cause or the effect. You will, however, even here, improve the condition of the limb with great care; but I would never advise recourse being had to the operation if the foot or other articulation can be brought into position by the efforts of the hand alone; but if by such continued efforts you are unable to restore the natural position of the foot, then divide the muscles, which, notwithstanding their spasmodic state, are contracted; and after the removal of the contraction, support the limb, and keep it as much as possible in a fixed position. I know of no cases that are more troublesome than these. It is a curious fact, that in these cases, where every muscle is affected, those of speech and deglutition as well, the intellects are perfect, although apparently weak, as

the cause must exist in the brain or its membranes, as well as in the spinal cord itself. The involuntary muscles are not in the slightest degree affected. The cause assigned, as in most other non-congenital cases, is generally dentition or cerebral irritation, and you will frequently find talipes valgus of the one foot, varus of the other; never, however, in their more severe forms, as the opponent muscles, although possessing less power, and thereby admitting of the malposition, are also in an active spasmodic state, and prevent the foot assuming the more severe malposition. This deformity is said to be congenital. I have never seen a case in an infant, and although the parents assert that such is the case, I shall not be satisfied until I see it, as I think it most improbable, except in hydrocephalic congenital states; but even here I have not yet seen it. In the paralytic also you will find one foot affected with talipes varus, the other with valgus, or calcaneo valgus; in fact, in either of the deformities I have mentioned, you will, in the spasmodic cases, which affect the whole of the muscles of the body, find contraction, either permanent or temporary, of the knees, and if not permanent, they will invariably be found on the flexed position on any attempt to exercise them on the part of the patient. The thighs will also be found adducted, and occasionally more or less contracted, in the flexed position; the pronators and flexors of the hand and arm preponderating in power, so that the patient can exercise no steady well-directed movement, nor even continue the position in which the hand or leg may happen to be placed; as, for instance, in the attempt to hold any thing in the hand, after having grasped the object, the hand will suddenly open with an irresistible impulse; nor has the patient any power to prevent this occurring.

It is clear, therefore, gentlemen, that we are in total ignorance of any complete and successful remedy for these cases; it is therefore useless to enter more into detail, as any thing that could be further advanced would be mere speculative theory. Galvanism has, in some cases of the less severe kind, been attended with partial success; but I much doubt if any positive beneficial results have eventually been obtained. You can, therefore, only place the joints in the relative position, and keep them in that position constantly, if the feelings of the patient will admit of it, but occasionally, from the violent spasmodic action of the muscles, you will find it necessary to intermit the treatment.

CONTRIBUTIONS
TO THE
PATHOLOGY OF THE BRAIN.

By S. SOLLÝ, ESQ., F.R.S.
Senior Assistant-Surgeon to St. Thomas's
Hospital, &c.

To the Editor of the Medical Gazette.

SIR,

I SHALL feel obliged by your inserting the following pathological facts, which I have had the opportunity of observing and recording through the kindness of my friends Dr. Conolly, and Dr. Begley, of Hanwell.—I am, sir,

Your obedient servant,

S. SOLLÝ.

St. Helen's Place, Nov. 1844.

The accounts which we have of the post-mortem examinations of the brains of idiots are not on the whole satisfactory, and it has not unfrequently happened that no morbid appearance could be discovered.

The record of them is useful; and though my views regarding the relation which in this case they bear to the mental condition of the patient during life may not be admitted by all, I trust they will induce others to pay particular attention to the condition of all the commissures, in their pathological examinations.

His general characteristics are thus detailed by Sir Alexander Morison, in his admirable work entitled the "Physiognomy of Mental Diseases," p. 221, accompanied by a most striking sketch of the appearance of the poor fellow during life.

This idiot is four feet six inches in height; his head does not differ much in size from the head of a sane person; it is rather depressed in the frontal portion.

The measurement of the head is—
 The circumference . . . 21 $\frac{5}{8}$ inches
 Occipital frontal curve . . 12 $\frac{1}{2}$ "
 Longitudinal diameter . . 7 $\frac{3}{4}$ "
 Transverse diameter . . 5 $\frac{1}{2}$ "

His lips are thick and his mouth is gaping, allowing the saliva to drop out of it; his teeth are good, but very irregular; his gait is awkward and unsteady; in walking he stoops forward, his knees a little bent, and his arms hanging before him as if he were about to fall; his usual position is that of leaning against a door and gently beating his head upon it.

He appears to possess the external senses—that of feeling is very obtuse; he cannot say any more than *tee teet*, which he frequently repeats, particularly in bed; he sleeps little; his temper is good; he is inclined to laugh, but in a very discordant manner; he can feed himself, but cannot dress or undress; he is inattentive to the calls of nature; he does not exhibit affection for any one, appears to have no sense of shame, and music does not excite any emotion in him. He is said to be inclined to onanism.

From Dr. Begley I received the following:—

Case of the Idiot Daniells.

“James Daniells (called George Daniells in the certificate) aged 33, single. His mother states that when she was eighteen years of age, and pregnant of the patient (her first child), she in walking through a street in Spitalfields, accidentally trod upon a rat which ran across the foot-path from under an old watchman's box: the animal on being trodden upon turned round and bit the heel of the narrator, who was much frightened, and swooned away, and in about a week afterwards was delivered of the patient, a seven months' child: the boy was fully formed and very healthy, and continued to be so till he was three years old: at that age he was seized with ‘convulsive fits,’ which lasted seven hours: on these subsiding he was found to have lost the use of his limbs, he could not walk nor stand, and his head fell to one side on his shoulders; he could not articulate; whereas, before this attack, he used to run about the house and talk like other children of that age; he used even to go to a neighbour's for sand, tape, a bellows, or any thing else that his mother might have sent him to borrow: he used to call ‘dada’ when he saw his father, and he addressed other persons by their proper names; but after this attack he appeared to lose all intelligence.

“She stated distinctly that they were not connected with dentition.

“Medical aid was resorted to without benefit: he became an out-patient of St. Thomas's Hospital under Dr. Currie: electricity was employed: the convulsions frequently returned, the narrator thinks most severely at the new moon; he was sent to school, but could not be

taught anything, and was very mischievous; he was kept at home until about 14 years ago, when he became so troublesome it was not possible to manage him; he was then sent to a private asylum, and some time afterwards to this institution. Narrator has had six other children, all of whom are sane and healthy.

“W. BEGLEY.

“Hanwell, Oct. 1844.”

Autopsy 30 hours after death.

The anterior portion of the skull-cap very much thickened, at least twice its natural thickness. The external surface of the dura mater more vascular than normal for the age of the patient. Slight sanguineous effusion diffused in small spots and patches on the arachnoidea reflexa lining the surface of the dura mater, not confined to the upper part, but extending to the base of the brain. This could be scraped off.

Some serous effusion underneath the arachnoidea investiens. I collected four ounces of sanguineo-serous fluid altogether, but a portion of this was from the ventricles. The anterior lobes of the brain rather smaller than usual; the convolutions generally small and narrow. The medullary substance of the brain rather vascular; hemispherical ganglion of natural colour. The *neurine* of the septum lucidum was entirely absent, and only the lining membrane of the ventricles left; so that all those longitudinal fibres of the fornix which run through and from that septum were deficient. Central portion of the fornix soft; the crura cerebri and both the thalami were also softened, but not discoloured.

Weight of cerebellum and medulla oblongata, six ounces two drachms.

Cerebrum, lb. ij. ʒij. ʒij.

Inflammation of both lungs,—of the pleura on the left side, with purulent effusion.

Slight inflammation of peritoneum.

REMARKS.—In considering the deductions we can legitimately draw from these post-mortem appearances, we must separate those which are recent from those which are of long standing, as the latter alone could have been the cause of the idiocy.

First, the thickness of the skull is common in all cases of atrophy of the brain from disease; the growth of the

skull following the shrinking of the brain. The hemispherical ganglion, which is now admitted to be that portion of the brain which more directly ministers to intellect than any other, was not altered in structure, which would have been the case if the skull had grown into, and thus pressed upon the brain; so that this condition of the skull must be regarded as the consequence, not the cause, of the condition of the brain which produced this idiotic state of mind.

The anterior lobes of the hemispherical ganglion, though small, were not so deficient as to account for idiocy, and the substance of the ganglion was healthy and natural.

The softening of the fornix and thalami was asthenic, and very possibly not very recent in its production: so that it appears that the only abnormal appearance which we can suppose to have been co-existent with the idiotic condition of the boy, is the deficiency of the medullary fibres of the septum lucidum. To those physiologists who regard this portion of the brain as a mere septum, this fact is of little interest; but to those who agree with me in regarding it as an important portion of the commissural apparatus of the hemispherical ganglion, the fact will be interesting. I find it necessary to advert to the fact that I demonstrated in my work on the Brain. (See page 186, and plate IX. fig. 1. and page 428, for physiological inferences, for pathological states), that the septum lucidum consists of longitudinal fibres, which, running backwards from the anterior portion of the hemispherical ganglion, form a portion of the inferior longitudinal commissure or fornix, for most writers on this subject since have neglected to observe it. And though physiologists may disagree with me in my view of the office of the septum lucidum as a portion of the intellectual apparatus, I know that they will find, if they take the trouble to examine it, that I am correct in my account of its anatomical structure and the direction of its component fibres.

I have long regarded, and taught in my lectures, that the commissures are the instruments by which impressions are conveyed between one portion of the hemispherical ganglion and another, just as the nerves are the instruments by which impressions are conveyed

from the external world to the brain. If a portion of the commissural apparatus be deficient, then, I believe, is the individual in whom the deficiency exists deprived of the means of comparing the impressions which his organs of sense convey to his brain; and consequently becomes idiotic from this serious defect in his mental apparatus.

It is very difficult to reason with any satisfaction upon the account of the progress of the idiotic condition of this lad from the mother's state, in relation of the condition of the brain after death. But the explanation which I should venture to propose is this. That about the age of three, the convulsive fits which occurred were occasioned by slight inflammation of the lining membrane of the ventricles, and some serous effusion into these cavities, and that absorption of the septum lucidum followed the subsidence of the attack.

It may be said that the idiocy was more probably occasioned by the serous effusion generally pressing on the hemispherical ganglion, and thus annihilating its function; but if such had been the case, would not this ganglion have been altered in structure?

OPIUM DETECTED IN THE STOMACH SEVERAL DAYS AFTER DEATH.

To the Editor of the Medical Gazette.

SIR,

I TRANSMIT the following case, which proves that opium may be detected in the stomach some days after death.

Samuel Cornish, aged 56, of previously good health, died somewhat suddenly on the 17th of September last. There were some suspicions of his having been poisoned, and I received notice from the coroner to be present at the disinterment of his body; he had been buried twelve days. The corpse was considerably decomposed, of a dark livid green colour, and the abdomen distended almost to bursting with gas. The chest and its contents were found to have been perfectly healthy; but on opening the abdomen it was observed that the whole course of the intestinal canal was highly vascular and congested, putting on a deep purple hue. The stomach contained about 1½ oz. of a thick dirty yellow

fluid; the intestines were quite empty, and, except at one point, free from ulceration. A part of the contents of the stomach was boiled in alcohol, and then filtered; it gave a deep red solution, which stained paper of a bright yellow tint; this was neither deepened or altered by alkalis, while nitric acid changed it to a purplish green: acetate of lead was added to the rest of the filtered liquid, and a copious precipitate obtained; the supernatant solution, when freed from lead by sulphuretted hydrogen, and evaporated nearly to dryness, gave with chloride of iron a greenish tint, and with nitric acid a bright red—two indications of the presence of morphia. The precipitate when diffused through water, and ridded of lead by sulphuretted hydrogen, was filtered and evaporated almost to dryness; it produced with a salt of iron a bright red colour, which was destroyed by nitric acid, potash, and proto-chloride of tin, but not by bichloride of mercury. It gave no colour with terechloride of gold, but white precipitates with lead and barium. From these I inferred the presence of meconic acid, and my former tests indicated saffron; other reagents proved the presence of carbonate of lime, but I could detect no mineral poison. The subsequent examination of the liver, however, proved the presence of arsenic.

It came out in course of the evidence that the deceased had died with symptoms of dysentery, and that the aromatic confection, with opium and chalk, had been administered. The chief feature of the case is, that opium may be detected some time after death. Other considerations are worth noticing here, viz. that the deceased had, in all probability, died from inflammation of the whole intestinal canal; but the upper portions of the small intestines were the most inflamed, and this, coupled with the absence of ulceration about the colon and rectum, indicated something more than dysentery; and but for the examination of the tissues, in which arsenic was found, the cause of this inflammation would have escaped notice.—I am, sir,

Your obedient servant,
H. LETHEBY, M.B.
Lecturer on Chemistry at the
London Hospital.

12, Tredegar Square.

CASE OF ACUTE POISONING BY CARBONATE OF LEAD.*

By JOHN SNOW,

Fellow of the Royal Medical and Chirurgical
Society.

(For the *London Medical Gazette*.)

I was called between 9 and 10 o'clock on Wednesday morning, the 8th of May last, to Henry Woodley, aged 5 years, living at 1, Rose Street, Soho, and found him suffering with symptoms of poisoning. I ascertained that, on the Saturday night previous, he had eaten some white-lead ground up with oil, which another boy had stolen, under the impression it was putty, from the door of an oil shop in the neighbourhood, where it was exposed for sale. The quantity he had was not larger than a marble, and he did not eat it all, as a small portion was found on the floor afterwards. He complained of bellyache the next morning, and his mother gave him a dose of salts and senna: this did not operate, and the pain in the abdomen still remaining on the following day, she gave him rhubarb and jalap, and afterwards castor oil, and the bowels were opened on Tuesday evening for the first time. The child's mother did not think his illness serious, and did not mention it to me, although I was attending her husband; she thought what he had eaten was only putty, which is not poisonous. During Tuesday night the pain in the belly greatly increased, and vomiting commenced for the first time. On Wednesday morning I saw the child as I have stated. He was in great pain, which he referred chiefly to the scrobiculus cordis; he vomited constantly a brownish liquid containing streaks of blood; his skin was hot, and his pulse 140 and hard; the face was swollen and of a purple colour; the conjunctivæ were red, not only from injection of the vessels, but from blood extravasated and coagulated beneath the membrane; the nostrils contained blood, and the body was spotted with petechiæ; the gums were tense, shrivelled, and milk white. Some leeches were applied to the epigastrium, and an emulsion containing Epsom salts was given. He passed some greenish-black semi-fluid

* This was related to the Westminster Medical Society, on the 19th inst.

motions of a very offensive odour. At 11 o'clock the pain continued, with occasional vomiting; the pulse was small and the extremities were getting cold; there was palpitation of the heart. At 1 o'clock, on injecting the bowels I found that there was complete relaxation of the sphincter ani. The pulse at the wrist ceased shortly afterwards, the tracheal r le set in, and he died at 2 o'clock, about ninety hours after taking the poison. The heart beat above 100 strokes after the respiration. There was no delirium or other lesion of intelligence.

An examination of the body was made eighteen hours after death, in which I was assisted by my friend Mr. Marshall, of Greek Street, who took notes of the appearances. The cuticle was loosened from a great portion of the body, and a quantity of serum flowed from the nostrils on moving the head. The gums presented the white appearance observed before death; the pericardium was filled with serum deeply tinged with blood, and each pleura contained several ounces of similar fluid. The heart was soft and flabby, and there was a little red fluid blood in the ventricles. There was ecchymosis of the surface of the lungs, and they were engorged posteriorly. There were two spots of ecchymosis beneath the mucous membrane of the  sophagus near its lower end; otherwise this tube was healthy. The stomach contained a little liquid similar to what had been vomited, and, throughout its entire extent, the mucous membrane was dark brown, swollen, and puffy, and there appeared to be extravasation of blood beneath it in addition to great injection of the vessels: this state did not extend to the duodenum or  sophagus. There was a bright red injection of part of the c cum, but the rest of the alimentary canal was of the natural pale colour, and was not contracted in any part. It contained a little clay-coloured fecal matter in the form of small pellets. The kidneys were large and flabby, and the liver, which was of a darkish colour, instead of presenting its usual firmness, was like soft leather; it could not, however, be torn with greater ease than natural. There was a peculiar odour about the body; not that of putrefaction. The head was not examined. The matters vomited, and those found in the stomach and intestines after death, and likewise the

substance of the stomach, were all subjected to a careful chemical examination, but no lead, or, indeed, any other poison, was detected.

Although slow poisoning by white lead is very common, occurring to painters, and several other classes of workmen who use it or manufacture it, acute or sudden poisoning by this, or indeed any other salt of lead, is not common. They are seldom chosen for murder or suicide, and, although extensively used in various trades, they do not often lie exposed, like arsenic or oxalic acid, in such a shape as to be mistaken for any article of food or medicine. In the few authors to whom I have referred, I have not met with any fatal instance of poisoning by a single dose of carbonate of lead. Mr. Taylor mentions, in his Jurisprudence, the case of a woman, attended by Mr. Cross, who took six or eight drams of it, by mistake, for magnesia, and recovered by the use of remedies. Orfila gave half an ounce of it to a dog, and it vomited several times within twelve minutes, and was no worse afterwards; and Dr. Christison quotes from a German journal the case of a young woman who swallowed accidentally an ounce and a half of it, without any bad effect, either at the time or afterwards. That it is very poisonous, however, we have sufficient evidence; for the carbonate is the form in which lead is introduced into the system of painters, and of most artisans who suffer from it, and, generally, of those who are poisoned by water impregnated with this metal. The morning after this child had taken the poison, his mother gave him, as it happened, some Epsom salts amongst senna tea. Now sulphate of magnesia is an antidote for the soluble salts of lead, but as it does not act on the carbonate at ordinary temperatures, it could only be of benefit by neutralizing any portion which might be decomposed by the acids of the stomach, and unabsorbed at the time. Several hours had already elapsed when it was administered, and as it was not repeated, we need not wonder that it did not stop the fatal effects of the poison. In addition to emetics and the stomach pump, Mr. Taylor very judiciously recommends the combination of some weak vegetable acid, as vinegar or lemon-juice, with solution of sulphate of soda or magnesia, in cases of acute poisoning by carbonate of lead.

From what I could learn, this child appeared for three days to suffer only from symptoms of lead colic, viz. pain and constipation of the bowels; and the intense and general gastritis of which he died would seem only to have commenced, or at least to have become severe, about twelve hours before death, as it was not till then that vomiting came on.

When I saw the child, which was not till within five hours of his death, he seemed to be labouring under all the effects of a corrosive or irritant poison, which one would have supposed had been taken only a few hours, instead of nearly four days. In the case I have quoted from Mr. Taylor, and in those I have seen recorded, of poisoning by the other salts of lead in large doses, vomiting, and other symptoms of violent gastric irritation, came on soon after the ingestion of the poison. The comparative mildness of the symptoms in this case for three days probably depended on the incorporation of the white lead into a tough mass with oil, which might retard its operation, and cause it to act only by degrees, in proportion as it became digested.

The white, tense, and contracted state of the gums, is worthy of notice. The gums were white and excoriated in a case of poisoning by the acetate of lead, quoted by Mr. Taylor, when the patient recovered. Acetate of lead is administered, occasionally, as a remedy in mercurial ptyalism. Dr. Burton has directed attention to a blue line on the gums in persons suffering under the chronic influence of lead; and I have, in two instances, seen the gums severely ulcerated in painters who had not been taking mercury.

No lead could be detected in the body after death, or in the matters vomited: but we need not be surprised at this, when we consider that the patient survived till the fifth day. It is a negative result that has been obtained in other cases of death from this poison. He had been vomiting several hours before any thing was saved for examination, and the fæces passed during life, which exhibited a peculiar dark colour, such as a mixture of sulphuret of lead with them might be supposed to occasion, were not subjected to analysis.

Frith Street, Soho, Oct. 1844.

ON THE TRANSFORMATION OF PUS CELLS INTO A MUCCOUS OR FIBROUS TISSUE.

By WILLIAM ADDISON, F.L.S.

[Continued from p. 73.]

III. *The Fibrous Tissue of the Saliva.*

ON referring the other day to a paper "On the Composition of Mucus*," published in the MEDICAL GAZETTE of July 29th, 1842, I found the following remark: "If mucus be treated with absolute, instead of dilute alcohol, it becomes coagulated, and in this state it is not possible to diffuse it through water." This remark suggested to me to try the saliva with alcohol (spirits of wine of the shops), and I made the following:—

EXP. 15.—A watch-glass was half filled with spirits of wine, and a quantity of frothy saliva collected in the month was allowed to fall into it: it was well stirred with the point of a needle, and in a short time the air-bubbles had burst and disappeared. A mass of white fibrous matter collected on the point of the needle, which when pressed quite flat and closely between two slips of glass, exhibited so coarse and tendinous a looking fibrous-tissue, that neither microscope nor lens were required to see it, and when rolled up a little between the fingers it was found exceedingly strong and elastic.

Dr. Kemp says, that if we compare the chemical formula of mucus with that of *protein*! we have—

He then goes on to notice "the remarkable resemblance of the chemical composition of mucus to that of the middle coat of the arteries;" and observes, "that bronchial polypi and the false membranes in croup are probably dense masses of altered mucus." From the above formula, I presume, looking at the results of my experiments chemically, we may conclude that both mucus and the saliva are hydrates of fibrine, alcohol, and the acetic acid, ab-

* By George Kemp, M.B. Pet. Coll. Cantab, Fellow of the Cambridge Philosophical Society.

stracting the water and precipitating the fibrine as an elastic fibrous-tissue.

Exp. 16.—A larger glass capsule was procured, and a larger quantity of saliva was made the subject of experiment; so that a much greater quantity of the fibrous tissue was formed. This was collected, and the alcohol allowed to drain out; afterwards it was placed in liquor potassæ for some hours, whereby it was reconverted, in great measure, into a transparent mucus. I conclude (still taking a chemical view of the results), therefore, that a strong watery solution of potassæ (liquor potassæ, *Brandish*) furnishes the requisite amount of water, and enables fibrine or fibrous tissue to resume the form of what in chemistry would be termed a hydrate (*i. e.* of a mucus), or when pus-cells burst under the influence of the alkali, the plastic element at once combines with water.

Now, according to my views of the process of secretion and nutrition,—and these views are, I contend, capable of as strict a demonstration as it is possible to conceive any other intricate inquiry to be,—according to my view, I say, the colourless blood, the pus, and the mucous corpuscles, are (essentially) living cells containing within them a plastic element (protein, if so it be) and living molecules: when the cell bursts the molecules retain their vitality, but the plastic element may become subject to chemical laws, either fibrillating and forming a fibrous tissue, leaving a residual albuminous material to mingle with the blood fluid, or combining with water to constitute a mucus. Thus far, and so on in the descending series, I can readily conceive that chemistry may aid us in our physiological difficulties, pointing out the changes which the elements of the tissues and secretions undergo when liberated from the immediate control of a vital power by the rupture or disintegration of the elementary cells; but we must either resign ourselves entirely to chemical views, and take their explanations as the basis of our physiology, or deny that chemical investigations can furnish us with all the knowledge we require in our endeavours to alter or to vary the elementary materials of the tissues and secretions while they yet remain inclosed within the body of a living cell, or in determining

certain vital operations going on within the cell, produce an element resulting in a fibrous tissue, a mucus, a tubercle, or a secretion.

I may be thought, perhaps, too warm an advocate for the microscope, when I contend that neither putrefaction nor fermentation are, strictly speaking, chemical operations; the results, indeed, come fairly within the province of chemistry, but these results can no more be obtained without cell-life, than a secretion*.

The science of chemistry was formerly limited to the changes and transformations of inorganic bodies, as contradistinguished from those due to the activity of a principle of life; but now the aspect of the science has changed, and from the extended views of its present eminent professors, it appears no longer confined within its former limits; they seek to bring within its sphere all the changes and metamorphoses of matter, whatever may be their kind or nature; and instead of our having an inorganic chemistry, and a vegetable and an animal physiology, we have substituted an inorganic, a vegetable, and an animal chemistry. If this be really what we are to come to, then let Liebig, or Dumas, give a new definition to the science.

I well know how utterly impossible it is to define the line between vegetable and animal organisms; still, no one would attempt to classify all living forms under the one or the other of these heads exclusively, calling them all vegetables, or all animals. So, likewise, it may be impossible to limit the explanations and doctrines of chemistry strictly to inorganic or lifeless matter, in any more satisfactory or definite manner; nevertheless, all those changes which we know to be produced by a vital principle, ought to be kept distinct from the domain of the chemical philosopher; otherwise, at once enlarge the boundaries of chemical science, and make it synonymous with physiology.

Great Malvern, Oct. 30, 1844.

* By cell-life, I here include those immeasurably minute, active, and voluntary moving forms, always, as far as my experience goes, to be found in every putrefactive matter.

PRACTICAL REFLECTIONS ON THE
CAPILLARIES OF THE HEAD.*

BY T. WILKINSON KING, F. R. C. S. E.

The Vascular columnar mass of the body has least distension above. The scalp and face differ. Weather-beaten aspects. Effects of a strong heart, &c. Polypus Nasi. Nævi. Epistaxis. Hæmoptysis. Apoplexy, &c. Lupus. Contracted Mouth. Normal nutritious equal—abnormal varying.†

VARIOUS considerations have led me to take up the subject of a not very old lecture; I think it deserves some attention from the profession, and I would hope that its introduction in this place may lead to useful comments on the part of those whose post it is to lead in the scientific treatment of disease.

The time is past for the chivalry of discussion, and the heroism of elocution. A plain printed page, like the modern coin, closely defines our notion of quantity, and leads most readily to a true estimate of the metal circulated‡. I shall rest tolerably well satisfied if my coin may pass for only legitimate copper.

The arteries and veins of the head are of remarkable comparative tenuity—they have least distension to resist; those of the feet have the most free nutrition. The sinuses of the dura mater may seem an exception to the idea of feeble canals, yet when we look a little further, and observe that a different set of tensions than tubular fullness exerts is the cause of their aponeurotic solidity, we find actually the venous tunics here reduced to the extreme of atrophy.

It may be thought that a column of

* Read before the "Physical Society" of Guy's Hospital, Oct. 5th, 1844. Some of the notes, &c., were not read.

† It is needless to shew that the following is an extension of views before advanced in the Medical Gazette. I deem it reasonable, however, to state that the precise relation of the present reflections to the main doctrines of Medicine, is explained in my "First general Laws," &c.; their connexion with Brain pathology I am already engaged with, and hope to explain further.

‡ Suppose, in the progress of events, a few more Journals, and a little more analytic summary of medical views in our Periodicals, and it seems to me that teaching will be resolved into tutorship, and Medical Societies will be devoted to coffee and compliments. A new order of things equal to the wants of 50,000 doctors appears already half accomplished.

blood, rarely amounting to one of six feet in vertical height, should cause but little difference in the vascular distension of parts. Poiseuille discovered none.* We do see, however, that position affects the circulation of each part of the body in health, and still more in disease. By day, an excess of distension operates below, a deficiency above. At night the balance is restored, compensation operates, repair is accomplished. Something might be gained by farther contrasting the states of the head with those of the feet, but I shall not try your patience to this extent. Catarrh, frontal caries, and tic, above; hydrocele, anasarca, varix, node, and gout, below; each the most frequent of its kind, may suggest all my meaning.

I shall not dwell upon the great numerical proportion of diseases of the head as a whole, but simply advert to such a series of changes, as will, I hope, establish the main proposition, that the peculiarities I speak of do exist, and have a direct practical import, as well as a general relative application to the changes in the entire body.

It would be natural, perhaps, to look towards the vertex of the head for the most constant and marked results of the vascular peculiarities we are considering; and I suppose these are seen in the silvered or bald head, and the glossy scalp at the period of declining life. Again, the most common of all

* "Not only does this equality of pressure exist throughout the arteries of the same vessel, but it is also similar in animals, differing considerably in magnitude and in strength. M. Poiseuille found that the hemodynamometer, when applied to the arteries of a dog, rabbit, or guinea-pig, indicated the same amount of pressure as when applied to those of the horse. So that a heart weighing one or more ounces transmits the same amount of pressure to the walls of the vessels as one weighing six or seven pounds." We must allow for defects in the instruments.

"The circumstances that modify the pressure of the blood, are, according to M. Magendie, referrible to two principal causes—the mass of liquid in movement, and the force of impulsion. We must also take most accurate note of the movement of respiration. M. Magendie found, in his experiments, that the force with which the blood moves in the arteries is diminished during inspiration, but augmented during expiration; and that during the action of coughing also the movement of the blood is accelerated. Hence, he remarks, the heart is 'the constant agent of the circulation; but the respiratory movements exercise so powerful an influence in this way, that during deep expiration the force that moves the arterial blood becomes almost double as great as in the normal state.' Lecture 6th."—*Hay's American Journal*, Nov. 30, p. 139.

leprons affections is that deteriorated production of cuticle which is hardly thought to be anormal.*

The scalp, however, in civilised life, and especially in females, is much protected, while neighbouring parts are habitually and unequally exposed, as well as more variously organised. In this respect, we might distinguish only two surfaces on the head, an anterior and a posterior: and in regarding the peculiarities of the face, I would look for causes of disorder; 1st, in the delicacy of its vessels; 2dly, in the variety of its functions; 3dly, in the circumstances of exposure.

We cannot but conclude that ruddiness must be very specific to be healthy; and, on the whole, perhaps, a certain general, but varying hue, inclined to red, is nearest to health. A well nourished capillary admits of increased injection with difficulty. The freckled and sunburnt hues depend of course on rete mucosum.

The cook, the coachman, the sailor, and the old Anglo-Indian, present different effects of facial exposure. I resolve all these into daily repeated deteriorations, and various healthy or irregular acts of repair. Moderate colour, and even surface, indicate normal changes, whilst wide capillaries, and turgid unequal surfaces, as well as atrophy, are parts of the less healthy weather-beaten aspect.

The hands are not less exposed in these cases, but their circulation is more uniform with, and their changes consequently more closely follow, those of the trunk.

It is worthy of remark, that although the face is the dial of expression, on account of its own internal workings, it is no less so from the incessant influences of remoter parts. Loss of blood, mere gravitation of blood and abstinence, tell first here; and these are not the only changes of vessels which are independent of local nerves.

I scarcely know if the power of the heart has been duly considered, with reference to these affections. From experience, I cannot impute great effects to ordinary venous obstruction, nor to simple hypertrophy of the left ventricle, but it may become more essential to reflect on these disturbed relations, when other disadvantageous

circumstances are concurrent. The softening of brain which so often precedes apoplexy is an acute or chronic nutritive change, and is numerically quite as much connected with visceral depurative defects as with disordered heart or arteries. Hypertrophy of a ventricle, like that of a biceps, depends on its labour, together with its nourishment. A thick ventricle, with diminished impediments, is a physiological anomaly: the whole heart must waste with declining exertion. Dilatation, or unhealthy hypertrophy, may be only increased impediments; and even much simple increase of power in the left ventricle, with settled obstruction in the ascending aorta, cannot augment the force of the circulation in the head in any case.

The occasions, however, in which the heart does operate mischievously on the head, are not, I conceive, few or trifling. We may find, at one time, a strong dilated labouring heart, by a little change of health, regaining a smaller size, and greater strength, without compensating changes elsewhere; and irregular repletion, exertion, exposure, and posture, may all combine, in addition, to increase a local evil, whether in the head, the lungs, or elsewhere.

A middle-aged man, with turgid, and almost livid face and hands, with or without palpitation, may be said to labour under congestion; or, rather, ill-nourished, and over-distended capillaries, with deficient excretions. Courses of medicine; with very little judgment, perhaps; or improved habits, restore him repeatedly. The same applies to simple palpitation, (I would almost say hourly): yet the case of a strong heart, and yielding capillaries, is not a mere supposition. The muscular diathesis, and the plethoric, are distinct. There may be universal congestion, and the feeblest muscular organs, and vice versâ. With great hypertrophy of the heart, we find pallor or lividity, a florid face, or deeply turgid capillaries.

In the older adult we may often find deteriorated, unequal hypertrophy, resulting from too free oscillations of nutrition; at least, I am persuaded that these expressions, if they do not totally explain the changes which we are all acquainted with, (vascular tubercle of the nose, &c.,) are yet fully consistent with the foregoing opinions; and I think they are in a measure indispen-

* *Pityriasis*.—Authorities advise good brushing, no brushing, &c. &c. Improvement depends on the nutritions from within.

sable to our philosophy, unless physics, as well as humoralism, are as nothing in disease. I apply the like explanations to the tumid nose and upper lip of youth.

Simple polypi of the nose are exceeded numerically by the like affections of the lining of the uterus, which, seem a kind of succedaneum for generation. The nasal mucous hypertrophy depends so much on diathesis, season, and climate, and even evinces so much subjection to internal remedies, that I venture to rank it as one distinguishing mark of the delicate, susceptible, and variable circulation of the summit of the vascular pile.

I think it is a fact, that obstinately increasing nævi and varicose arteries affect the head in particular, and we ought to remember that good nutrition is the direct means of reducing all blood-vessels to a normal mean, and settled relative proportion. This does not apply less to polypus, tumid tonsil, "relaxed" sore throat, and the hoarseness of debility.

Many physicians may feel disinclined to regard epistaxis as an important disease, but in this place I wish to make the most of it. Why are the nasal vessels more prone to yield than any others in the body? Shall we suppose weakness, or obstruction, or excessive impulse? I conceive the first to be often, and perhaps constantly, the real state, and would consequently avail myself of the warning, if only to anticipate other signs of constitutional debility. It is not true that such vessels usually give way from genuine plethora; nor is it ever right to refer a local change to a general state exclusively.

I suspect that the first hæmorrhage of decline is often from the larynx.

I infer this with more or less confidence under the following circumstances. If it be fairly observed, that the red sputum be coughed up, however easily; if one only out of several portions of mucus, or few out of many, be streaked or tinged with blood; if the blood have a fresh appearance, and not a brown colour; if it be in small quantity, and little mixed with accompanying mucus; if coughed up after exerting the voice, (only a few spoonfuls perhaps), fresh looking, and (blood having trickled down into the lung,) if the subsequent expectoration be at first more clotted, but then for

three or four days less and less dyed, but more brown, and gradually replaced by the variable catarrhal mucus of disordered health.

There are, I suspect, chronic diseases of the sacculi laryngis. A patient may detect uneasiness here, and every two or three days may void (at intervals) a pair of mucous masses, more or less stale, offensive, or rough to the taste, and dull or dark, or even variously tinged with pus or old blood, or brightly streaked red. The blood-tinged sputa of settled phthisis is still distinct from the preceding. It has no specific source. The copious hæmoptysis of the more healthy may yet be only laryngeal. There are, I find of late, most abundant proofs amongst authors, that the bleeding which rather frequently concludes phthisis is from a large ulcerated vessel. These observations are of most value with respect to the earlier signs of disordered nutrition, a due attention to which, and obviating the causes of variable decline, may be attended with the happiest results.

To return to my immediate subject. The most common spontaneous extravasations of blood are in the head; and the like occur in the eye, orbit, and face.*

The common catarrh, sore-throat, wasting of the gums, and of the face, all seem to me to depend for precedence on their comparative disadvantages as to site.

Lupus exedens is amongst the rare yet marked peculiarities of the face. One of its grand characteristics is a distinct and repeated transitory act of cicatrization; and indeed, the evidences of reparative power in this protracted disorder are hardly second to those of simply failing nutrition; the two alternate, and may be nearly equal for years. Here, I think, we discover the specific trait of the disease. No kind of adventitious tubercle. Ill-nourished scaly skin; a blotch, the centre of which may or may not die; a pustule devoid of power to make a projection—tardy ulceration and repair, and this repeatedly. I should be very much struck to find, as some describe, cicatrization on one side of a sore and ulceration on another, and the two *progressing* through the very same hour, instead of succeeding each other. The nose may

* A small spontaneous ecchymosis in the eyelid adds great significance to a doubtful fit.

often be said to be shrunken rather than eaten away. What a striking indication of oscillating nutritive balance in the general body! How strong a suggestion, that the high and solitary promontory is feeble as well as exposed; seeing it alone of all the body suffers thus! Though all indicates a cachexia, countless successive wounds and rubs elsewhere may be repaired fully.

It is of course too plain, that in process of time ulceration, or I would rather say atrophy, prevails. The health and the disease get worse and worse without the need of debilitating remedies, as alteratives, &c. Very long, and perhaps the only feature of the case throughout, is scanty and deteriorated nutrition. I do not know that this may not include all the specific disease. The patient dies with the feeblest serous inflammations, and perhaps, effusions.

It may at least illustrate my meaning, to prescribe recumbency, and even such practices as scrubbing floors, for these patients. May not local applications be too much like exposure?

I cannot but regard this view of Noli as a new and essential part (the zero) of a great systematic arrangement of all the forms of organized tubercle classed as cancer.

Mr. Liston has given an account of herpes exedens in a recent lecture in the *Lancet*, and advises free escharotics. It is evident that he does not fully distinguish the case devoid of tubercle and hypertrophy; and he sufficiently distrusts the complete efficacy of the remedies. It is but a small thing for me to differ from this gentleman's opinion, but I would strongly urge the simple view of remedying the failing nourishment in the specific case.

There are cases which look almost as much like deteriorated nutrition as deficiency: I allude to the rare and extreme contraction of the mouth, which at last appears almost as a pin-hole. Here is evidently some atrophy, but some induration. The change is attributed to mercury, &c. The disorder seems to become stationary with improved health, but it is hardly curable. Forceful extension is only aggravation.

It must appear that I have not made out a very strong case: I may, indeed, admit that I should fear to attempt so much. The physiologist may think the first view of my case very feeble,

but I do not suppose that the pathologist can entirely reject it. The truth is, that in health the different degrees of vascular tension, and consequent nutrition, in different parts of the body, ought to be difficult of detection. Where the nutrient molecular changes proceed with vigour and firmness, all should seem equal; if any part be weakened its pure restoration should be speedy: yet abstinence will shew itself first in the face and mind; and the capillaries most concerned will necessarily yield the more to the new restoring afflux until the due balance is again in a manner fixed*.

* It may not be amiss to subjoin, without discussing, some views of M. Magendie, who is one great advocate of physical and humoral things in medicine.

"Every one is aware," he remarks, "that during very hot weather the face is more highly coloured than at other times, and the movements of the heart more rapid. A greater quantity of blood is constantly passing through the vessels, and the cutaneous and pulmonary exhalations are very sensibly increased in quantity; hence the craving we feel for aqueous drinks, in order to restore to the blood the water it is constantly losing. But it is on the capillary circulation more especially that the temperature of the blood exercises a very manifest influence." * * "The variation of heat acts not only on the blood in the capillary vessels, but dilates the membranous walls of the latter, enlarges their cavity, and modifies the hydrodynamic phenomena. Pulsations are felt where they did not exist before; several globules now pass abreast in the tubes, which before scarcely allowed of the passage of one; in a word, a new state of things discloses itself for the investigation of the physiologist."

"When the practitioner wishes to increase the activity of the circulation in an individual, and facilitate the passage of the blood through the whole vascular system, he orders a warm bath; its effects are soon felt through the entire frame. The respiration becomes accelerated, because, as a greater quantity of oxygen is required, the tissues swell, and the external surface grows red. Again, if the object be to diminish the activity of, for example, the cerebral circulation, and to increase that of distant parts, you make use of pediluvia. The phenomena ensuing are precisely the same as in the preceding case, except that they are simply local. Instead of acting on the entire vascular system, you limit the action of the elevated temperature to a few of its tubes. This, too, is an exclusively physical result. Let us take an example of the opposite kind. An individual puts his hands and feet in snow: the fingers and toes immediately become white, in consequence of the reflux of blood to the central parts of the limbs. The capillaries of the periphery of the body, when submitted to the action of sudden cold, become unfit for carrying on the circulation. Part of the fluid they contain passes into the veins, and, as they no longer admit that which the arteries carry to them, they are really for a moment empty."

This M. Poiseuille has proved by direct experiment. "Cold baths," observes the lecturer, "are recommended in cases where the indication is to soothe general excitement, characterised by excessive activity of the circulation. When the forehead burns, and the temporal arteries beat violently, we apply ice, or some frigorific fluid, to the part. When too much blood flows to the brain, we have recourse to cold affusion." * * "The treatment of fractured limbs by constant irriga-

Let it be granted that in syncope all sanguine supplies are failing; yet may we not decide that the top of the blood-tubes suffers most? Let us turn, now, to those minor oscillations of visible imperfect nutrition in the head, which coming and going in cachectic and delicate persons, ever variously throughout the day, betoken almost as much power of repair as actual delicacy, especially if we consider that the constitutional weakness is only kept up by repeated mischiefs from without, which judgment, or even accident, may, and does,

tion with cold water, furnishes another example of this mode of action. The prolonged continuance of a low temperature diminishes the vascular pressure, prevents blood from rushing in the natural quantity towards the seat of the lesion; in a word, prevents the phenomena called inflammatory from taking place. When we plunge into cold water during very warm weather, a peculiar sort of constriction is felt at the thorax. This, again, is a purely physical phenomenon. Less blood traverses the capillaries, consequently it accumulates in greater quantities in the larger trunks; these, distended as they are, press on the neighbouring organs; hence the uncomfortable sensation of which the patient is conscious. It disappears when the equilibrium is restored throughout the sanguineous system; and so the sudden immersion of the whole body renders its effects much less sensible."

In proceeding to consider the circulation through the capillaries, the lecturer notices, first, the extreme minuteness of these vessels, and the peculiar properties of the blood which enables it to traverse tubes of so small a calibre.

The diameter of the capillary vessels has been computed to be about the 1-150th, or 1-200th of a millimeter—(a millimeter equals the 0.039370th of an inch.) Now it is with the greatest difficulty we can succeed in forcing water, or any analogous fluid, through glass tubes only 1-10th of a millimeter in diameter; and it is almost impossible to drive a liquid through tubes of a smaller diameter, no matter what force be employed. We meet with the same resistance in injecting water into the mesenteric artery of a frog, with a view to force its passage into the continuous vein. The fluid employed is, in a great part, extravasated into the surrounding tissues, and but a small quantity reaches the desired point.

"My inquiries up to the present time," the lecturer remarks, "go to prove, that the passage of the blood from the arterial to the venous capillaries is effected by means of a nice adaptation of its physical properties to the physical endowments of the vessels." * * "That if a single one of the properties of that fluid be modified, its movement throughout the capillary system becomes impossible."

It is to the viscosity of the blood, mainly, that M. Magendie attributes its capacity to traverse the capillary vessels. The viscosity of the blood he pronounces an indispensable condition for its free circulation. This property he illustrates by experiments on inorganic tubes. Thus, notwithstanding the impossibility of introducing water into a tube of extremely small diameter, whatever force we employ, yet if any mucilaginous substance, as gum, gelatine, or albumen, be added to the water, it may be injected with ease. This fact is proved by some ingenious researches of M. Poiseuille."—*Hay's American Journal*, Nov. 1839, p. 145-7.

remove in thousands of instances. I allude particularly to the complaints of the young adult—suffusion after eating, the blushing nose, blotchy affections, tooth-ache, and a considerable number of other varying or transitory affections in the way of pain or vascular injection.

Why are they of short duration; not persisting from bad to worse? Why do we so often find them capable of arrest in any stage of their course? To sum up: I would suppose fluid stores within, varying as to quantity and quality—external exposures also changing, and still more, the wear of every part by turns*. I suppose the loss of solid or of fluid to be in a great measure the cause and regulator of its own restoration. When disease comes, the readiness with which the head suffers is peculiar. Gravity and other causes affect other parts in a peculiar manner, and for specific reasons†.

ANALYSES AND NOTICES OF BOOKS.

"L'auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALEMBERT.

Guy's Hospital Reports, Second Series. No. IV. Oct. 1844.

THE present number opens with the communication from Mr. Alfred S. Taylor, of the case of a male child, aged 14 months, who died eighteen hours after taking an overdose of a sleeping mixture administered by its nurse. Powdered opium had been put into a phial, hot water poured upon it, and after well shaking, a tea-spoonful of the contents was given, and repeated at short intervals till about three and a half tea-spoonfuls, containing not less than three grains, and probably more, of opium had on the whole been taken, when the child speedily became quiet, and fell asleep. It awoke so far as to take some milk six hours afterwards, but soon went to sleep again, and nothing further was observed till the morning, nearly twelve hours after the first dose, when it was found breathing very hard. A medical man, who was

* See a paper on Variable Disorders, &c. *Guy's Hospital Reports*, No. 11.

† See a View of the Humoralism of "Urinary Structure," five papers in the *Lancet*, 1843-44.

called in, found the child perfectly unconscious, the breathing stertorous, the hands slightly convulsed, and the eyes covered with a thick film. All his efforts to remove the insensibility, and remove the symptoms, were unavailing, and the child died eighteen hours after taking the first tea-spoonful.

The remaining contents of the phial, and about a drachm of "a white thick viscid liquid, without any particular smell," which was removed from the stomach, also some liquid from the small intestines, were preserved for analysis, and led Mr. Taylor to institute a series of experiments upon questions relative to criminal poisoning by opium which may arise, and which occupy the larger portion of his communication. The analyses and experiments, and their results, are presented to the profession in the lucid style and logical manner which so strongly characterizes the writings of this eminent medical jurist. The details comprise, 1st, an inquiry into the solubility of opium in water; 2dly, the difficulties connected with the analysis of morphia and meconic acid, and the most striking chemical properties of those two bodies; 3dly, the relative power or delicacy of the tests for morphia, with the smallest quantity of that alkaloid susceptible of detection; 4thly, the degree of solubility of meconic acid in water; 5thly, the limit of the power of a salt of lead to precipitate and separate meconic acid in opiate mixtures; and 6thly, the smallest quantity of meconic acid susceptible of detection, either free or combined with the oxide of lead, and by inference the smallest quantity of opium. Opium was readily detected in the mixture, but was not discoverable in the fluids removed from the body. Mr. Taylor informs us, that owing to the facility with which opium may be procured, and the improper use of the drug, cases of poisoning by it constitute about one-third of all those that come before the coroner; and that "Parliamentary returns shew that the deaths from opium throughout England and Wales are not less than one hundred per annum; and this great mortality from one poison occurs chiefly among infants and young children."

talis, and its uses in diseases of the heart, with some general rules for the employment of this drug, originally read before the Physical Society of Guy's Hospital. These conclusions are drawn from more than 400 observations, originally commenced at the suggestion of Dr. Bree, and made during a five years' official connection with the St. John's Hospital, the Farringdon and the Tower Hamlets Dispensaries. In 184 cases the drug was administered alone, or in vehicles incapable of modifying its action—a circumstance requiring notice, as the author "knows no medicine whose effects are more modified by prescriptive combination than digitalis."

Dr. Munk considers sedative action on the heart, and diuretic influence, as the two best marked, and indeed the only, properties of digitalis. The former influence is of two kinds, the depressing and the antispasmodic. The depressing action is best secured by the exhibition of the tincture alone; the antispasmodic by the combination of the tincture with camphor, assafoetida, galbanum, ammonia, or other antispasmodics; while the diuretic property is seldom or never advantageously obtained but by the infusion. The powder he finds uncertain and unmanageable; and of the peculiarities of the extract, recently admitted into the Pharmacopœia, if it contain any save that of uncertainty, he has no personal knowledge or favourable impression from the statement of friends who have employed it. He believes the poisonous symptoms, which in a few instances have occasioned death, only become developed when the drug fails to act in its normal manner as a diuretic or sedative: once these effects kindly induced, the medicine may be continued with safety for a considerable period. If these effects are not evidenced in a few days, there is danger of its accumulation, and the appearance of its poisonous symptoms. Of this influence, from over-dose of the infusion, an instructive case appeared in our pages in August last.

The next paper, by Dr. Munk, contains conclusions on the action of digi-

CICERO.

ADDRESS OF THE SOCIETY OF APOTHECARIES*.

THIS pamphlet is an able exposition of "The Bill"; and having it to refer to, no one need err from want of a guide through the intricate mazes of that measure, or blind himself longer to the effects which its becoming law would almost certainly have upon the position of the great body of the medical profession in these countries. The only fault of the Address, in our opinion, is, that it is pitched in too low a key. When men feel that they have been treated unhandsomely, they speak with more of *verve*, and in accents that are louder than wont; and such a style carries conviction to the mind of the listener that the speaker is in earnest. It is not otherwise with writing; the hand is an index of the state of the mind even as true as is the tongue, and burning words fix themselves on paper, and find their way to the heart, nearly with the same force through the chambers of the eye, that they do through the porches of the ear. The Address is somewhat tame, then; but, because it is free from passion, its logic, it may be believed, is by so much the better; if the oratory be less, the reasoning is more; if feeling be wanting, truth stands there unveiled, without disguise. He who wrote the Address is a very able man, and has not belied the con-

fidence which his brethren of the Worshipful Society of Apothecaries have placed in him.

In our comment on the "Statement of their Administration of the Apothecaries' Act," by the Worshipful Society, we expressed dissent from their assumption of the large measure of credit to which they there lay claim in the progress and improvement of the science and practice of medicine: we believe that progress, that improvement, to have been totally unconnected with the existence of the Society of Apothecaries, and with any one of their enactments, or with all of them put together. It would not be fair, probably, to say that the Society had rather stood in the way of improvement, "though we will stand accountable for as great a sin as that too"; we are persuaded and know that the profession at large have got beyond the Apothecaries' Company and their requirements: the general practitioner, who is the representative of that respectable body among the better, as they are called, or more educated classes, is all but invariably the Member of the Royal College of Surgeons as well as the Licentiate of Apothecaries' Hall. Society, and the progress of medical science, required more than did the Law and the Examiners of Apothecaries' Hall, and he therefore aimed at, and aiming at achieved, the higher grade of surgeon in addition to his title of apothecary.

In its "Statement," the Society declared that in their judgment the scope and tendency of the Bill for the Regulation of Medical Practice was to degrade, if not to destroy, the class of general practitioners." In this Address they have sought to show that it is so in fact. Now although we are also afraid that the bill of Sir James Graham would have such an effect, we have the misfortune still to differ with the Worshipful Company as to the cause of

* An Address by the Society of Apothecaries to the General Practitioners of England and Wales, on the Provisions of the Bill "For the Better Regulation of Medical Practice throughout the United Kingdom," and their probable influence on the Position and Prospects of that Branch of the Medical Profession. 8vo. London, pp. 55. Hightley.

this; we do not believe that the conclusion they point at is to come "because it is proposed to take away the power from them of controlling the education and conducting the examination of their own class"; nor yet because the Bill "would repeal the checks upon the practice of unqualified persons, without substituting any provisions by which such persons might be prevented from practising in future."

In connection with the first of these points, what is the fact? That it is not, and never has been, held any honour to belong to the Apothecaries' Society; the practitioner of medicine has gained nothing in public status or estimation by his forced association with that body; he has much rather connected himself with it as a positive evil: the license was indispensable to him as a legal title to practise, and therefore he took it—never of free will and choice. He never paraded himself before the world as the apothecary; it was always as the surgeon. When no honour is gained by a title, or by following a particular course prescribed, then none can be lost by abstaining from that title, by ceasing to pursue the line chalked out. The profession of medicine has been advancing with at least as rapid strides on the Continent, in France and Germany, and in America, as it has in England, and in none of these countries have men in the grade of the Court of Examiners of the Worshipful Society of Apothecaries one word to say in the examination of the practitioner of medicine; and if there be enactments against unlicensed practitioners in the continent of the old world, there are none in force in poor Scotland, where cheapness is necessarily a great consideration, nor in many of the States of the American Union. It is, in fact, the long and intimate connection between the profession of medicine and the trading Company of

Apothecaries that has occasioned much of the difficulty that is now experienced in reference to unlicensed practitioners in England and Wales: a state of things has here been engendered which exists no where else, and which brings it to pass that the example of Scotland and America in this respect cannot safely be followed in England. A large proportion of even the educated classes in England at this moment think that he who deals in drugs knows as a matter of course how to prescribe them.

"The Society disclaim any intention of imputing to the right honourable gentleman by whom the Bill has been introduced, that he desired what the Bill (if it become a law) will assuredly bring about. He has been obliged to derive his information on the subject on which he proposes to legislate from others; but that his advisers can be ignorant of the tendency of the Bill which they have counselled, it is hardly possible to believe; for if the avowed object had been to depreciate the standard of qualification of the general practitioner of medicine, to lower his professional status, and to diminish his claim to public confidence, it would be difficult to have devised a measure better adapted to the purpose."

We agree with the Society in this particular; but wherefore—how—has this New Medical Bill any such effect? Not, we opine, because it contemplates the extinction of Apothecaries' Society as guardians of the education and judges of the competency of the future practitioner of medicine, but because it cuts him off from each and every one of the time-hallowed institutions that are connected with medical science in the public mind, from association with establishments where the heads of the profession, the great high priests of Æsculapius, must still be congregated, and proposes to leave him a kind of lopped branch of the medical

tree—an abscissa of the medical profession, properly so called; upon a footing with the licensed victualler in society, or at most with the licensed attorney, whose name is sharpset, and in the lowest grade is tantamount to knave and pettifogger. This is the degradation which the Bill, if it does not contemplate, would nevertheless, we think, effect. To suppose, however, that in the present day any such measure can be carried through the two Houses of Parliament of Great Britain, against the sense and opinion, and interests, of such a body as the general practitioners of medicine of England, Members of the Royal College of Surgeons, and Graduates in Medicine of the University of Edinburgh, in the majority of instances, as well as Licentiates of Apothecaries' Society, seems to us an absurdity. By ruse or finesse, by trick or chicane, in days gone by, such a measure might by possibility have been carried through, and have lived a session or two; but forewarned is forearmed in such a case, and with free tongues and unfettered pens, and the steam press at their back, the members of the medical profession, if true to themselves—by which we mean in all that is for the general, not for any peculiar advantage—may not only bid defiance to their enemies, but being roused they need not now quit them till they have discomfited them utterly.

"In every civilized community," says the author of the Address, "the health of the people is a subject of common interest, and in proportion as any state advances in civilization, the regard for human life is more strongly marked, and its preservation becomes an object of greater solicitude, and a duty of more acknowledged obligation. This regard for the public health is the principle recognized in the preamble of the present Bill, and is the principle upon

which we understand all medical legislation to be founded." Unquestionably; but what does the new Bill in connection with this position: "it sweeps away, in a single clause, the whole of the preceding legislation of the country, every provision, wherever found, which imposes any restriction on the practice of medicine and surgery." (p. 10.)

It certainly is a *new* principle, that ignorant pretenders to medical skill are to be allowed to pursue their dangerous practice with impunity, and to have it declared by a deliberate act of the legislature that it has ceased to be an offence against the law of the land for them to tamper with the health of the community.

The Bill, however, is not in harmony with itself in all its parts: no one is to be held competent to hold any public medical appointment who is not a legally qualified practitioner. The author of the Address handles this portion of his subject very ably; and truly we are bound to say that, like the "Phoca" in the Antiquary, the apothecary "has the best of it."

The author of the Address next proceeds to discuss the constitution of the Council of Health and Education, which he, of course, complains of as having no representative from among the great body of general practitioners. "The principle of representation," he says, "seems to be recognized in the constitution of the Council: the Crown will be represented; the Universities will be represented; the Physicians and Surgeons of England, Scotland, and Ireland will be represented; the General Practitioners alone are not represented, though they must needs have their wishes to express, and their grievances to be redressed." We have repeatedly argued for the constitution of the medical profession as made up essentially of two classes of practitioners, physicians and surgeons, or of these two blended in

the same individual, as he is in the army and navy, with whom we associate the chemist and druggist as dispenser of prescriptions. The argument of the author of this Address only gains weight from the want of incorporation of the general practitioners as a body; did they not feel themselves cut off from all connection with either of the Royal Colleges they would not complain of their non-representation in the Council of Health and Education. It seems to us, indeed, that the author of the Address does not distinguish with sufficient nicety between the general practitioner, the member of the College of Surgeons and licentiate of the Apothecaries' Society, and the simple licentiate of Apothecaries' Hall. As champion of that establishment he ought to have confined himself to its licentiates. The examining board at Apothecaries' Hall, almost to a man, are members of the Royal College of Surgeons: let them use all their efforts to secure an honourable and equal connection with that corporation, and as associates there they will be represented. Did they stoop to comply with the conditions imposed by the Council of the Royal College, and present themselves in Lincoln's Inn Fields for examination, we do not imagine that the examining board there would be hard-hearted enough to reject any of them. We should very much enjoy being present at the examination, especially if the terms could be so arranged as would permit the examiner and the candidate to propound a question turn and turn about. The surgeons would probably have the best of it in connection with the origins and insertions of muscles, but on chemistry and botany, and the materia medica, the apothecaries would almost surely come off victorious.

But still it is not, perhaps, altogether fair in the apothecaries' advocate to say that they have been wholly

and entirely forgotten in the Bill: is there not the Calvinistic remnant of the Court of Examiners of the Apothecaries' Society to be saved by being tacked on to help the College of Physicians? We have always looked on this as one of the master-strokes in the Bill. Its authors obviously thought the apothecaries, with their *present privileges*, needless; their existence, as a body, controlling the education, and testing the qualification, of the medical practitioner as an anomaly in the present day, and they have been anxious to get rid of them in the least unkind and offensive way; they have therefore done them the honour to tack them on, as we have said, to the Royal College of Physicians.

The author of the Address then proceeds to argue, that the standard of qualification of the general practitioner has been greatly elevated; that the education required of him is of the very highest kind; and that the improvement has mainly taken place under the auspices of the Court of Examiners of the Apothecaries' Society. "The College of Physicians have not hitherto felt it to be their duty to superintend the education or examination of the general practitioner, and would be ready to disclaim any share in its past control." No doubt; but the College of Physicians have had nothing to do with the education of the general practitioner—we published only last week our opinion, that we thought it matter of deep regret that the College of Physicians had not had this control all along.

The author of the Address having next shewn that the education and examination of the general practitioner is left entirely in the hands of the Colleges of Physicians and Surgeons, proceeds to argue that the public will suffer from this arrangement, on the presumption "that the class which is in possession of the fuller measure of

public confidence, on the ground of superior attainments, has a direct interest in preserving *as marked a distinction as possible* between the attainments of their own class and that of the class below them." (p. 29.)

"Now if the public at large have an interest in the class of general practitioners being as highly qualified for the discharge of their duties as the present state of medical knowledge will allow of their becoming, is it wise, is it safe, to intrust the duty of their education and examination to the exclusive direction of those whose interest lies in directly the opposite direction? Never let it be forgotten that it was with the general practitioner himself that the demand for an improved standard of professional qualification for those of his own class originated, and that it is the general practitioner who has raised that standard to what it now is. The general practitioner has a direct interest in improving the standard of qualification, and thereby extending the sphere of usefulness, and raising the professional status of his own class. The interest of the physicians as a body, is directly opposed to this improvement and elevation of the general practitioner. The difficulty this view of the subject presents to the examination of the general practitioner by the physician has been felt and acknowledged by members of that body, because it cannot fail to render the duty an invidious one, and there will always be this anomaly attending its discharge—that in proportion as the duty of giving a high qualification to the general practitioner is performed with zeal and efficiency, will the physicians be breaking down the distinction which exists between the class which they are educating and themselves—that distinction upon which their very existence, as a separate class, depends.

"Looking at the constitution of the governing body of the College of Surgeons, the same reasoning applies, and with equal force, to the share which that body is to take in the education of the general practitioner.

"But it will be said, You ought not to impute to the Colleges of Physicians and Surgeons, that in the exercise of the powers proposed to be given them by this Bill, they will be actuated by a desire to lower the standard of attainment of the general practitioners, or check their improvement as a class. We reply, that our objection to the Bill is, that it gives them the *power* of doing so."

But we must pause in our quotations and comments upon this very ably written address, by far the best examination of the Medical Bill that has yet been produced. We beg to recommend it in the strongest terms to all classes of our readers, to our country friends in especial, who, to our poor apprehension, seem to want enlightenment on the measure most wofully. They too commonly shew themselves "innocent rusticals" in their mode of looking at the measure. Let them put on the spectacles with which the Apothecaries' Society supply them in this Address, and look at the thing, narrowly, curiously, and, without thinking too much of the interests of this class or that class, of this body or that body, consider the medical profession as a whole, and ask themselves how its important functions with reference to the community at large are likely to be affected by the purposed legislation.

MOVEMENT IN THE PROFESSION.

PLEASE God, there is some prospect of calm for us again! We have notices of fewer meetings this last week than we have had for a long time. It may be that the *great* meeting of the Provincial Medical and Surgical Association, as it has been designated, has

suspended all the lesser meetings. The grand meeting took place at Derby, on the 14th—Dr. Robertson, of Northampton, in the chair; and everything seems to have gone off very amicably and well. The sense of this most respectable and numerous meeting will be completely gathered from the resolutions they passed, which we append entire. The only amendment proposed, we think, was by Mr. Martin, of Reigate, and it was in favour of the Apothecaries' Society; but it was coldly received: and though it found a seconder, not more than a single hand was held up for it when it was put from the chair. The Apothecaries' Society, we fancy, must see this as a kind of hand writing on the wall. The general practitioners, in the provinces at least, do not wish to be associated or identified with Apothecaries' Hall. The medical profession has, in fact, outlived the state of things that made this necessary. The resolutions adopted at the Derby meeting are these:—

1. "That the Association testify their satisfaction that a bill for the better regulation of Medical Education and Practice has been laid before the House of Commons, and that opportunity is afforded to the members of the medical profession for considering its provisions previous to its passing into a law."

2. "That this satisfaction is increased by observing that an approach to a uniform standard of education and qualification, and the right to practise by all qualified persons, without respect to local privileges—principles for the recognition of which the Association has on various occasions contended, and especially in petitions to the Legislature, and memorials to her Majesty's Government,—are two of the great leading principles of the measure."

3. "That further to ensure the object of a sufficient uniform primary qualification for every medical practitioner, without which the equal right to practise every department of the profession ought not to be conceded, it seems desirable that the diploma of Licentiate of Medicine should be required of all who may hereafter propose to enter the profession, and previous to their being entitled to claim admission to register in any other grade."

4. "That these principles, if carried fully into effect, would confer a great benefit on the profession and the public, in the removal of many existing evils; and that, in thus providing the public with a supply of fully qualified medical practitioners, the Association are of opinion the Government would do much towards the remedy of abuses of

which, for a long time past, there has been great reason to complain."

5. "That the Association view with alarm and deep regret that part of the bill which proposes to abolish all restriction on the practice of medicine by unqualified and unlicensed persons; and that, although there may be some reason to doubt the practicability of altogether preventing unlicensed practice by general enactment, the Association are of opinion that the illegality of such practice should be unequivocally declared, and some simple and effective means of restraint be adopted."

6. "That while the Association approve, with this exception, the general spirit and principles of the bill, they feel that in various details it may be desirable to introduce certain changes and modifications, which would improve the general efficiency of the measure, and tend materially to facilitate its practical application."

7. "That while the Association is sensible of the advantages which the profession will derive from a direct connection with the Government, they cannot but consider the proposed constitution of the 'Council of Health' as deficient, in not affording express representation, either of the physicians and surgeons resident in the provinces, or of the great body of general practitioners throughout the country."

8. "That some provision ought to be made, either in the bill, or in amended charters to be granted to the Colleges of Physicians and Surgeons, for a more direct acknowledgment of the representative system in the councils or governing bodies of these corporations."

9. "That in the absence of any provision for the admission of the general practitioners into a participation, on terms honourable to that body, in the corporate privileges of either of the Colleges of Physicians and Surgeons, it appears essential to the well-being of this numerous and influential body, as well as beneficial to the public interests, that they should be incorporated together, and that the interests of such corporation should be adequately represented in the proposed Council of Health."

On Friday last, the 15th instant, a meeting of the members of the medical profession of Maidstone and its vicinity took place, Dr. Sibbald in the chair. Resolutions were passed expressive of satisfaction that the legislature should at length have made the medical profession the subject of a special and comprehensive legislative enactment; approving of many of the provisions of the Bill, but believing that extensive modification in others will be required before it is permitted to become

law. Suggesting that the great body of general practitioners must be represented in the Council of Health. Approving the principle of a uniform and efficient course of education, and of the system of registration, but opining that it should be compulsory. And requiring "that some penal enactment of easy application, whereby summary punishment, by fine or imprisonment," may be dealt out to the unqualified should they pretend to practise physic, may be appended.

The editor of the "Maidstone and South Eastern Gazette," which has been kindly sent to us, we observe, makes the following remarks:—

"With reference to the suppression of what are called quack medicines and secret remedies, in our humble opinion this can never be done by legislation, but must be left to be dealt with by the increasing intelligence of the people."

In looking down his advertising columns in search of the medical resolutions, we were struck with the very considerable number of advertisements of quack medicines, a list of which we append as a matter of curiosity, and to enable our readers to judge for themselves whether the editor and proprietors of the Maidstone and South Eastern Gazette would be likely to relish any measure that should put an end to quackery and quack medicine-vending in every shape: here is the list in one number of the Gazette:—

1. THE HAIR.—"Rowland's Macassar," of course—but that perhaps is a cosmetic; 2. Dr. Grandison's Charity Pills; 3. Holloway's Pills; 4. Ford's Pectoral Balsam of Horehound; 5. Robinson's Patent Barley and Groats—though these perhaps are dietetic, yet are they "recommended by the Faculty." 6. Stirling's Pills; 7. The Ninth Edition: Manly Vigour, &c.; 8. The Twenty-first Thousand: Manhood, &c.; 9. The Thirteenth Edition: The Silent Friend, &c.; 10. The Cordial Balm of Syriacum; 11. Perry's Purifying Specific Pills; 12. Whooping-Cough: Farley's Never-Failing Remedy; 13. Woodhouse's Æthereal Essence of Ginger; and 14. Balsam of Spermaceti; 15. Dr. Sibly's Reanimating Solar Tincture; 16. and, lastly, Snook's Aperient Family Pills. This is pretty well, we should say, for one newspaper, and worth fifteen pounds if worth a penny.

BETHLEM HOSPITAL.

At a quarterly Court of Governors of the Royal Hospitals of Bridewell and Bethlem, held on the 18th instant, "a report from a general committee, with a scheme for regulating the admission of two pupils from the Royal Hospitals of St. Bartholomew and St. Thomas, to attend the physicians of Bethlem Hospital, when receiving and visiting the patients therein," was received and adopted.

The scheme referred to will be immediately carried into operation; and the ample wards of Bethlem Hospital will thus become not merely the means of charity to the sufferers from cerebral disease, but of instruction to successive generations of the most intelligent and zealous pupils of the two other Royal Hospitals. The sharp eyes of intelligent pupils have also an admirable effect on the way in which the medical duties of every hospital—of such an establishment as Bethlem Hospital in especial—are performed. The President of Bridewell and Bethlem Hospitals, Sir Peter Laurie, has been unwearied in his exertions to render these noble institutions all that the most enlightened philanthropy would have them, and, supported by the Treasurer, has long shewn that he had an open ear for every thing in the shape of improvement which experience could suggest. Large sums have lately been expended, are still in the course of expenditure, at Bethlem, with a view to render the house a true *curative* establishment. What a different aspect has Bethlem now to what we remember it some twenty years ago! We visited it last week, and actually saw that in the whole of the immense building there *was not a single individual under restraint!* The exception used to be, to find an individual who was not in the strait waistcoat. Well has our distinguished friend, Dr. Marx, said, and we love to quote him:—"Sympathy with man in his afflictions, the devotion which in utter unselfishness makes sacrifice of itself, never put forth fairer blossoms than do many among our present establishments for the treatment of insanity."*

* Decrease of Disease, &c. p. 16.

QUEEN'S COLLEGE, BIRMINGHAM.

THERE seems little doubt but that in this College there is already laid the foundation of a great and flourishing University. Its supporters from the very outset have been unremitting in their efforts to advance its prospects; and, so far as we know, all is done in a spirit and with a purpose that must insure the very largest ultimate measure of success. The Rev. Vaughan Thomas, in particular, has been most zealous in the cause, and, assisted by a munificent donation from Dr. Warneford, a chapel has lately been built in connection with the College, which was consecrated on the 15th instant, by the Bishop of the diocese.

The Rev. Mr. Thomas assured the large and distinguished assembly present on the occasion, that Dr. Warneford regarded the consecration of the chapel of their College as the consummation of his most anxious and pious hopes in a great and holy cause; for well might he deem that cause great and holy, which had for its object the giving the stamp of Christian character to the studies of professional youth, imparting the beauty of holiness to their lives, and making the temple of science the sanctuary of religion. Although their kind benefactor was not amongst them in person, he was present in spirit; his eye was ever on their school; his heart was with them—that heart, which ever throbbed with the pulsations of Christian love, the love of God and man, and everything that was calculated to promote the glory of his Creator, and the good of his fellow-men.

The Lord Bishop said it was his greatest pleasure, and he might at the same time say his bounden duty, to attend in all parts of his diocese, and on every occasion in which his presence might be useful in the promotion of religion or scriptural education; but more especially so amongst those who were young, and entering on the world, exposed alike to its follies and temptations.

The President said, that they would be guilty of a very manifest omission, did they separate without also tendering their grateful thanks to Mr. Sands Cox, who had laboured, he might almost say, day and night, in order to

promote the interests of the institution, and more especially in carrying out the plan for the erection of a chapel in connection with the Queen's College.

NOTE FROM SIR B. BRODIE.

To the Editor of the Medical Gazette.

SIR,

IN the leading article of the *MEDICAL GAZETTE* of Friday last I find a scheme propounded for the incorporation of the great body of general medical practitioners with the London College of Physicians, and followed by these observations:—

“The plan suggested would have this further advantage; it would not be opposed by those who have been prime movers in the construction of the Medical Bill. We threw it out to the distinguished individual who has the credit or the discredit, according to different men's views, of the projected Bill; and his reply was, ‘Let the College of Physicians take them, and welcome,’—meaning the general practitioners.”

It is evident that this refers to a conversation which I had with you on Thursday, the 7th of this month; and I have no doubt that there are few of your readers who do not understand that I am the individual alluded to.

The expression attributed to me, standing as it does alone, cannot but be regarded as offensive to two classes of persons, whom I equally esteem, and among whom I have met with some of my kindest friends, the College of Physicians and the general practitioners. But you must be aware that it was not so intended, and that it would not have been so considered by others, if the rest of our conversation had been recorded. I am willing to believe that it was only through inadvertence that you quoted any part of a conversation that was purely confidential. Having done so, however, I have a right to expect that you should go further still; and with this view I beg to remind you of what happened, so far as it concerns the remark in question.

On that day, which I have mentioned, I had an interview with you on a subject which concerned yourself.

I was influenced by no other motive than a feeling of kindness towards you, and a desire to prevent your being placed in what would have been, at any rate, a disagreeable position.

In the course of our communication you observed, speaking of the general practitioners, "They are more of physicians than of surgeons;" and you then suggested that the College of Physicians might make them an appendage of their body. I scarcely knew whether this was to be taken seriously or not, it being, indeed, plain that it would not suit the views either of one party or of the other, and I answered, carelessly enough, that "they were welcome to do so if they pleased." I said this, not having the smallest notion that it was to be put forth to the world as my grave opinion, and certainly without any kind of disrespectful feeling either to the general practitioner or the physician.—I am, sir,

Your obedient servant,

B. C. BRODIE.

14, Saville Row, Nov. 16, 1844.

[It is due to Sir Benjamin Brodie that his letter should appear in the *MEDICAL GAZETTE*, and at the same time we cannot but express our regret that any remark which he feels to have been confidential should have been inserted in our pages, and in a form not precisely as it appears to have been expressed by him at the time.—*ED. GAZ.*]

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Tuesday, November 12th, 1844.

MR. STANLEY IN THE CHAIR.

THIS was the first meeting of the session; there was a very numerous attendance of fellows and visitors. On taking the Chair, Mr. Stanley briefly addressed the assembly on the prosperous condition of the Society, and alluded to the last volume of Transactions, just published, as sustaining the character of the previous volumes. He briefly drew attention to an addition which had been made to the Library, in the busts of several of the Presidents, which were placed in appropriate positions around the room. The busts already received are those of Halford, Earle, Babington, Cline, Abernethy, Brodie, and Travers.

Case of Ulceration of the Duodenum, in which the gall-bladder was filled with a

colourless aqueous fluid, and contained numerous gall-stones. By C. J. ROBERTS, M.D., Physician to the Welsh Charity, &c.

THE author only saw this case a short time previous to death. The patient was attacked with violent vomiting on Tuesday evening, which resisted all the means employed to subdue it, and he sank on the following Thursday, at two o'clock, P. M. On examination after death, the intestines were very slightly glued together by lymph. The inner membrane of the stomach had many ecchymotic spots on it of a very deep colour. The duodenum was ulcerated through its entire length; the liver small, but healthy; the gall bladder was distended, and at its apex there was a small vesicle more translucent than the other portions of the bladder, looking as if from a rent of the two outer coats, and a protrusion of the inner one. On opening it, more than 4 oz. of a perfectly limpid transparent fluid escaped, but unfortunately none of it could be collected for examination. There were more than a hundred gall stones in the gall bladder, about the size of peas. The kidneys and bladders were healthy.

The author remarks that cases where a number of gall stones have been found after death, without their presence causing irritation, or being suspected, are not rare; but that the total absence of bile, or rather its place being supplied by an aqueous fluid, are not common. He observes, however, that allusions are made to it by some of the older authors, as Fernelius and Haller, and also that mention is made of an altered condition of the biliary secretion, by Andral, and by Drs. Graves and Stokes, as well as by Dr. Thomson, in his Practical Treatise on Diseases of the Liver.

He concludes by observing that the most extraordinary part of the case is, the fact that the man never made any complaint of hepatic derangement during life-time. He was never jaundiced, nor had pain in the right side, notwithstanding one of the calculi was firmly grasped by the duct.

Case in which the Vena Cava Inferior was obstructed from the commencement of the common iliac veins, and its cavity obliterated between the entrance of the emulgent and hepatic veins. By THOS. BEVILL PEACOCK, M.D.

THIS was a case of complete obstruction of the inferior cava, from the uterine and common iliac veins to the entrance of those from the liver. The obstruction in the former vessels, and the inferior portion of the cava, was the result of the adherent masses of pale lymph, while above, the ves-

sel was converted into a ligamentous cord. The right kidney was in an advanced stage of granular degeneration, the left completely atrophied; the liver was also of small size. The author considered the disease of the vein to have been wholly unconnected with the death of the patient, and ascribed the general dropsy under which she laboured during the last period of her life, to the condition of the kidney and liver. The circulation had been maintained by means of the branches of the vena azygos. The author was of opinion that the adhesions of the uterus to the adjacent organs, and the appearances of the veins, as exhibited in the preparations shewn to the Society, were conclusive of the dependence of the obstruction in the vein on inflammation of the vascular tunics.

Mr. Stanley pointed out the features of interest in Dr. Peacock's paper; viz., the obliteration of the inferior vena cava, and the substitution of a collateral circulation by means of a great enlargement in the vena azygos, without any perceptible increase in size of the superficial abdominal veins.

Dr. Budd remarked that although we were well acquainted with the effects of adhesive phlebitis when occurring in the veins of the extremities, we had not sufficiently attended to the influence of this disease in producing atrophy of the glandular organs. The paper before the Society seemed to him to bear on this subject. He (Dr. Budd) had seen instances in which both the liver and kidney had become atrophied to a great extent from the presence of adhesive phlebitis in the portal and renal veins. He had seen the liver so atrophied as to be indented with deep fissures, and on examination it was found that the branches of the portal veins supplying the atrophied parts were completely obliterated, as the result of phlebitis. He had seen the same effects in the kidney from a like cause.

Mr. Stanley referred to two cases of adhesive phlebitis, which occurred in St. Bartholomew's Hospital: in one, the popliteal vein, in the other, the veins of the arm, were affected with phlebitis, as was evidenced by all the signs and symptoms of that disease; and yet after a time the circulation in the affected veins was completely restored. He inquired if any member present had seen similar cases?

Dr. J. C. B. Williams considered that the pathology of the veins was not sufficiently understood. He took occasion to refer with commendation to Mr. Paget's Paper, published some time since, on this branch of pathology, and related a case in illustration. It was an instance in which disease of the veins existed at the same time with disease of the lung. The physical

signs were those of pleuro-pneumonia affecting two-thirds of one lung. The symptoms, however, were too severe to be explained simply by this condition, for not only was there extreme difficulty and obstruction in the breathing, but the countenance was remarkably livid, and the œdema of lower extremities rapidly supervened. The patient died, and on examination two lobes of the right lung were in a state of complete carnification, and on being divided by the knife were found to be very red in the interior. The pulmonary veins were much enlarged, and were found to be obstructed by the adherence of large clots to the lining membrane. The vena cava ascendens, and other important veins in the body, were affected in a similar manner, and yet there was no evidence whatever of any recent inflammatory action; on the contrary, the lining membrane was paler and softer than usual, and contained patches of atheromatous deposit. This fact, taken in connection with others of a somewhat similar kind, had led him to consider that many cases supposed to be phlebitis were not so in reality, but that the symptoms presented to us depended on an adherence of the fibrine of the blood, or of coagula, to the coats of vessels, which by the influence of previous disease had become roughened. If we reasoned by analogy, there was good ground to suppose the doctrine correct, for it was well known that the lining membrane of arteries became altered by old age, or some other cause, totally independent of inflammation.

Mr. Fergusson had met with two cases of obstruction in the venæ cavæ, one of the superior, the other of the inferior vein. The first case occurred in a subject in the dissecting-room, and in this instance the collateral circulation had been carried on by the vena azygos greatly enlarged, assisted by the branches which communicate with it. This case bore out the description given by Dr. Peacock in his case, as to the influence of the azygos vein in carrying on the circulation. In the second of these cases, the patient had died three weeks after giving birth to a child, and although she was attended by observant and skilful practitioners, no idea had been entertained by them of the true nature of the case; neither, indeed, were there any symptoms to guide them to an accurate diagnosis. On examination after death, nothing at first was discovered to explain the fatal result. The parts in the neighbourhood of the spine were subsequently examined, and it was then found that the inferior cava was completely blocked up with lymph; it also contained pus in its interior, and there was pus also on its outer surface.

• With respect to Mr. Stanley's inquiry, the speaker referred to cases in which varicose

veins of the lower extremities had been attempted to be obliterated by the passage of needles under, and string over them. In many cases there was every indication of inflammation having been established; yet, after the expiration of ten, twenty, or forty days, the blood commenced to flow again through these vessels. Cases of the kind were not uncommon, and had probably been seen by many present. These cases had led him to believe, contrary to the common opinion, that adhesive inflammation of the lining membrane of veins was by no means an usual occurrence, nor easily set up.

Dr. Peacock did not agree with Dr. Budd, with respect to the influence of adhesive inflammation on the atrophy of the glandular organs. In his own case he felt convinced that the glandular disease had preceded that in the veins. Besides, the liver in this instance was atrophied, whilst the portal venous system was healthy. The atrophy of the kidney of one side depended on granular degeneration, and the enlargement of the other had its origin in the same disease in a less advanced stage. He considered, in his case, that there were unequivocal proofs that the morbid appearances in the veins were the result of adhesive phlebitis.

Mr. Snow referred the origin of the adhesive phlebitis in Dr. Peacock's case to inflammation of the uterus, in which the veins of that organ had become involved, the disease consequently spreading to the larger vessels. The state of the uterus and its morbid adhesions proved that inflammation had existed in it at some some previous time. Mr. Fergusson's last case illustrated the same point.

On the Classification, Structure, and Development of the Echinococcus Hominis; showing reasons for regarding it as a species of Cysticercus. By ERASMUS WILSON, Esq. Consulting Surgeon to the St. Pancras Infirmary; Lecturer on Anatomy and Physiology in the Middlesex Hospital.

The author agrees in the opinion, now become general, of the universality of this curious entozoon in the sacs of the common acephalocyst, but differs with all preceding writers in regarding it as a fixed or pedunculate animal, in its perfect state, as well as in its undeveloped form. The cases in which it was observed were the common hydatid tumor of the liver; the little animal measures in its longest diameter from $\frac{1}{20}$ to $\frac{1}{12}$ of an inch in diameter, is scarcely distinguishable by the naked eye, and is enclosed in clusters of from two to one hundred in a proper membrane, which is developed from and attached by a point to the internal membrane of the acephalocyst. To give an idea of the number of echinococci con-

tained within an hydatid tumor, the author counted their number in an acephalocyst of about the size of a hazel nut. In this small cyst he found forty clusters, several of which contained eighty individuals, and the entire number of separate echinococci was about one thousand. The animal is found in two states, namely, a contracted and an elongated state; in the latter there is perceived a circle of hooklets at the cephalic extremity, with four suckorial processes; then follows a cyst-like body or caudal portion, into which the cephalic portion is drawn in the contracted state, and at the caudal extremity is the peduncle. After giving a minute description of the structure of the animal, the author proceeds to describe the changes which take place in the creature after death, and gives a full account of the progressive stages of its development. The author considers the offices of the hooklets and suckorial processes to be involved in obscurity, the creatures having neither mouth, nor organs of progression. The identity of structure of the echinococcus with the cysticercus, he considers to be complete, and proposes for it the name of *cysticercus pedunculatus*. The paper was accompanied by upwards of forty well executed figures, drawn to a scale.

Dr. Budd bore out the accuracy of Mr. Wilson's description of the echinococcus, having had repeated opportunities of examining this animalcule in the hydatid cysts of sheep and man. The more curious circumstance relating to this minute being, was the discovery of M. Livois, that it was a mere parasite, but that it was invariably found in hydatid cysts, and that it was, moreover, the cause of these cysts. M. Livois had founded this opinion on the examination of a very large number of cases. With the view of testing this opinion, Dr. Budd had examined seven hydatid tumors, which had been for many years in the museum at King's College. In some of these he experienced difficulty in discovering the animalcule, but succeeded in finding the teeth, which appeared to be the last part of the creature liable to decay. In two cases no trace of the echinococcus could be found, but this was explained in the one instance by the circumstance of the hydatid cyst having been expectorated and burst, and its contents escaping; and in the other, by the cyst having been everted and the echinococci washed away. It was a curious circumstance, that the echinococci were precisely the same in the hydatid cysts in man and animals, although the cysts themselves in these two existed under such different circumstances.

PHYSICAL SOCIETY OF GUY'S HOSPITAL.

BRANSBY B. COOPER, Esq. in the Chair.

November 16, 1844.

A LARGE meeting of this Society was occupied in hearing and discussing a paper read by Dr. Barlow, in which he gave a connected description of the views entertained by himself, and which he has previously put forth, in reference to the depuration of the blood. This depuration, he conceives, is wholly effected by the two-fold agency of air and water. The atmospheric air acting through the medium of the pulmonary circulation, removes, in the form of carbonic acid, the carbon which has been formed in the capillaries of the aortic circulation, and which would act as a poison if returned to the left side of the heart, and was again transmitted through the system. The water acts through the medium of the portal circulation, by the capillaries of which it is taken up from the stomach and small intestine, and is employed for the purpose of holding in solution the solid contents of the bile, the urine, and the perspiration, preparatory to their elimination by respective secreting organs, and without which these solid contents cannot be separated from the body, unless they are brought to the emunctories in a state of solution.

These views were lucidly stated and supported, by references to the symptoms, pathology, and effects of remedies employed in cardiac, hepatic, and renal disease, and also to dropsical effusion in the peritoneum, and to the symptoms and state of the blood in Asiatic cholera; Dr. Barlow dwelling particularly on the impossibility of procuring diuresis when disease of the liver had proceeded so far as to materially obstruct the entrance of water from the small intestine into the portal circulation.

A pretty active discussion ensued, in which Drs. Birkett, Brereton, Addison, Hughes, and Mr. Hilton, took part. Dr. Birkett could not entirely adopt opinions which made secretion entirely depend on the quantity of water present or imbibed into the system. Dr. Brereton and Dr. Hughes criticised the cases brought forward in support, and also the facts adduced from the cholera, and thought they were insufficient to establish the theories advanced. Dr. Addison eulogised the paper, and felt generally disposed to concur in its conclusions, but saw difficulties in the explanation offered of the phenomena of the renal secretion in hepatic disease. For instance, the urine in the hobnail liver disease was small in quantity, but normal in the proportion of its constituents, while the urine in active congestion and enlargement of the liver was not only in small quantity, but also over-

charged with solid matter. The obstruction to the entrance of water through the portal system was equal in both cases, and yet the result on the renal function was different. Could this be explained?

Mr. Hilton thought Dr. Barlow had entirely overlooked the entrance of fluid into the system by the absorbent system—a channel as important as that of the portal system. The President inquired of Mr. Hilton whether in the course of his inquiries he had been able to connect any particular symptoms with the inter-lobular, or intra-lobular forms of venous congestion of the liver, so as to aid their diagnosis during life, and was answered in the negative.

After the customary vote of thanks to the author, he adjourned the meeting, and announced a case of subclavian aneurism by Mr. —, as the subject for the next discussion.

LUMBAR ENTEROTOMY,

WITHOUT OPENING THE PERITONEUM, PERFORMED WITH SUCCESS UPON A WOMAN, AGED 53.

By J. S. AMUSSAT.

MADAME B —, 53 years of age, of sound constitution, had enjoyed good health habitually until within the last four months, when she began to be troubled with obstinate constipation, and occasionally to suffer severe cholicky pains. Two months back, these pains became still more severe and frequent, and the fæces passed, with the assistance of injections, were slender, flattened, ribbon-like, and surrounded with mucus and blood; discharges from the bowels became more and more difficult; clysters began to fail in their effect, and the patient was compelled to have recourse to castor oil, aloetic pills, &c. From the 12th of June there was no longer any evacuation from the bowels, nor any expulsion of flatus, in spite of castor oil, croton oil, purgative clysters, &c. The belly became distended and tympanitic, and vomiting was superadded to the other symptoms; there had been complete constipation for a fortnight before I was called into consultation with Dr. Seddillot and M. Marjolin, who had done everything that art suggested, and had already thought of having recourse to an operation. The belly was now distended with flatus, and generally tympanitic; no tumor could be discovered by palpating; the finger in the rectum met with no obstruction. On the 27th of June the patient was no better; nothing had passed from the bowels. 28th, same state; the abdomen, measured round the umbilicus, was upwards of 32 inches and a half in circumference. The establishment of an artificial anus seemed every way indicated if the patient was to have a chance for her life; but entirely ignorant of the seat of obstruction, we knew not how to

proceed. Were we to open the colon in the left lumbar region, or were we to proceed to the same operation on the right side? The history of the patient led us to conclude that we had not to do with any acute stricture of the bowel, nor with one situated at any great distance above the rectum. It is also well known that organic diseases of the great intestine, causing tympanitis and retention of the fæces, are commonly situated at the point where the sigmoid flexure of the colon ends in the rectum. We entertained the hope that the seat of the obstruction might be there. We had but one means of guessing at, or approximating to the fact, however, which was, by measuring the quantity of fluid that could be introduced in the way of lavement. On making this experiment, it was found that the patient received and retained readily the whole of an ordinary syringe, and one-third of a syringeful of injection; more than this could not be forced into the bowel: the obstruction could not be seated very high, therefore.

30th.—Same state.

July 1st.—In consultation with Sir Philip Crampton, of Dublin, who happened to be upon a visit to Paris, and several distinguished French practitioners, Sir Philip, upon the invitation of his French medical colleagues, gave it as his opinion that if the operation for artificial anus was performed, it ought to be done without loss of time; his own personal experience did not allow him to decide upon the value of the measure, but he was inclined to approve of it from the cases which M. Amussat had published. All things considered, then, the propriety of the operation decided on, M. Amussat determined to perform it on the left side.

Having marked with ink the space bounded by the os ilium below, by the edge of the first false rib above, and by the edge of the common mass of the sacro-lumbar and long dorsal muscles behind, I made, says M. Amussat, a transverse incision in the middle of this space, between three or four inches in length, and which I gradually deepened until I had reached the aponeurosis of the transversalis. Three small arteries, divided in this first stage of the operation, were twisted; I then cautiously divided the aponeurosis mentioned; immediately a large pellet or mass of fat escaped by the opening made, upon cutting through which I saw a portion of the intestine, red, and tense. To ascertain whether or not this portion of the intestine belonged to the colon, which it was my purpose to open, I carefully explored the parts, and came to the conclusion that it must be part of the colon, inasmuch as the quadratus lumborum, which was exposed on its outer edge, shewed the relations with the bowel which we know to be natural. I therefore determined to transfix the portion of bowel in question, with a curved needle

duly armed with a waxed thread behind the point at which I believed the peritoneum to terminate. I then fixed a tenaculum in the intestine, and with a pair of curved scissors divided the intestine between the tenaculum and the thread. Immediately there was a rush of gas from the bowel, and soon afterwards an escape of yellow feculent matter. Having now attained the object which I had proposed, I enlarged the opening by means of the scissors without any fear, and gave free vent to the gas and fæces. The patient immediately felt great relief from the evacuation. To terminate the operation, which had succeeded thus far beyond my utmost hopes, and was much more easily executed than I could have anticipated, I fixed the intestine to the skin anteriorly by means of three points of uninterrupted suture. An injection thrown in by the artificial opening facilitated the escape of feculent matter. The operation was admirably borne by the patient. Put to bed when she had been cleaned, her pulse was neither stronger nor weaker, quicker nor slower, than it was before having been placed upon the table.

Evening.—No sickness; perfect calm; abundant escape of fæces by the wound. Next morning, pulse 80-85; and several hours sleep, which the patient had not had for ten or twelve days, refreshed her greatly.

July 3d.—All going on well; on the 4th, escape of flatus per anum, and on the 6th and following days, not only of flatus but of fæces, in small quantity, however, not sufficient to encourage the hope that the natural passage would be restored. A month after the operation, the wound is cicatrized; the artificial anus is kept plugged with a mass of wax, and the state of the patient leaves no solicitude in regard to her permanent recovery: there is no indication of organic disease that can bring her life into jeopardy.—*Gazette Medicale de Paris*, Aug. 10, 1844.

[We have given the case as reported, and with the original title; but, as we understand it, the intestine was entered not behind the peritoneum, but through it; M. Amussat was in doubt whether the red, distended piece of intestine that presented itself at the wound was the colon or small intestine, which he would never have been had he known himself without the peritoneal cavity in the situation where he was cutting.—ED.]

ACTION OF THE HEART.

THE frequency of the heart's movements during convalescence from continued fever, and their gradual abatement under the influence of a nourishing diet, are constant and generally admitted facts. Physiologists, however, are not agreed upon their cause; according to some, the heart only continues

to obey habits contracted during the course of the fever, which wear out as convalescence advances. According to others, who consider every febrile movement to be accompanied by a certain degree of irritation of the internal membrane of the heart—a shade of endocarditis—the frequency of the pulse depends on the persistence of that modification after the removal of the causes which gave rise to it. I have some difficulty in admitting either of these theories; the first appears to be contradicted by the rapidity with which all the other functions are re-established with the commencement of true convalescence; and as regards the second, if the internal membrane of the heart retained the irritation, after the subsidence of the fever, it ought to be increased rather than diminished by the contact of blood richer each day in stimulating materials; and if the frequency of the pulse were an indication of that state of irritation, it should increase instead of diminishing, when we give nourishment.

The following appears to me a more correct explanation. As soon as the febrile orgasm subsides, and the functions resume their regular exercise, the want of nourishment is felt in all parts of the system; this is evidenced by the rapidity with which the nutritive materials in reserve in the adipose tissue are absorbed, giving rise to that rapid emaciation which we see constantly take place in the first days of convalescence. All the tissues now demand at once the supply of blood necessary for their reparation; and being unable to obtain it, either because the mass of blood is absolutely diminished, or, being altered in its composition, has become inadequate to the reparation, the movements of the heart are accelerated, so as to make up by the frequency of the supply what is wanting in the abundance. The more, therefore, the quantity of blood is increased, and the more its quality is improved by the introduction and elaboration in the alimentary canal of nutritious materials, the more do the heart's movements abate. In like manner, after abundant hæmorrhages, we see the circulation at first become accelerated without fever actually existing, or having existed, and diminish in frequency when the mass of the blood has increased, or regained its normal composition.—Dr. FALLOT, in *Annales Médicales Belges*, 1843.

CASE OF INJURY OF THE HEAD.

On the 10th of January, I was called to a man, about 25 years of age, whom I found surrounded by a crowd of curious people, who partly gave utterance to feelings of pity, and partly believing him mad, were making various preparations to restrain him. He had shortly before been knocked down by an oaken plank, 8 feet long, and 3 feet

thick, which had fallen from a height of 18 feet upon his head. On examining the skull, which I did with great difficulty, in consequence of his opposition, I found a depression $2\frac{1}{2}$ inches long, by $1\frac{1}{2}$ inch broad, and $\frac{5}{16}$ ths of an inch deep, in the situation of the anterior and superior angle of the right parietal bone. There was no other external injury. The look of the patient was furious, his eyes rolled in his head, and he frequently gnashed his teeth; on his face evidences of bleeding from the nose were apparent; nothing else unusual. The pulse was small, depressed, and so slow that it scarcely beat 60 strokes in a minute. To questions the patient only answered by nodding or shaking his head, and by gestures pointing to his tongue, his neck, and his windpipe, that he had lost the power of speech. His walk was so insecure, that he had to support himself by the furniture in the room. He resolutely opposed my preparations to bleed him, drew the form of a leech upon the table with his finger, held up four fingers to indicate the number four, and pointing to the wounded head, indicated that he wished to have them applied there. It cost me great trouble to make him comprehend the greater usefulness of venesection in such circumstances. He made me understand by signs that I should take no more blood from him than a single cupful; when this quantity had flowed, he became impatient, and insisted upon having the arm bound up; I, on my part, wishing to get away a larger quantity of blood, felt the pulse, and used other pretexts to let a larger quantity flow; the by-standers also came to the patient's assistance, and insisted upon my tying up his arm. In my disputes, first with the patient and then with his friends, from twelve to sixteen ounces of blood might have flowed, when the patient suddenly exclaimed "now tie up my arm." This excited great astonishment among the spectators, and I was compelled to yield to his desire, although the frequency and the fullness which the pulse now shewed would have led me to leave the vein open for some time longer. The arm was tied up, and the patient put to bed, having a poultice of cold vinegar and water applied to the part injured, and an aperient mixture of arnica flowers, senna leaves, and sulphate of magnesia, prescribed for him every hour, until free discharges from the bowels should follow. In the evening the bowels had been moved twice; the pulse was free and large, and of proper frequency; the patient only complained of some lassitude, but the speech was slow and halted when he got at all excited. He had some sleep in the day; the wounded part was hot and moderately painful. Next day, the patient was up,—I found him standing by the stove making his poultice. He now questioned the fact of any depres-

sion of the skull—he was only aware of some swelling—and showed great disposition to go to work. On the 15th, indeed, in spite of all my dissuasions, he went to work, and has continued very well ever since, although he cannot now get a few feet above the surface of the ground without feeling giddy. By and by, he discovered that the skull was actually depressed in the situation indicated.

He says that he felt himself knocked down by the falling plank, but that he immediately rose again possessed of complete consciousness, and had gone on about five paces, when he fell a second time senseless, nor did he recover himself again until he found himself at home. His anger had been excited by feeling himself without the power of speaking, and the disposition in the by-standers to treat him like a madman: he had a feeling of constriction and stiffness, which extended over the lower jaw, the tongue, and the neck down to the breast; the tongue appeared to have become motionless by its weight and thickness, so that speech would not follow the strongest behests of the will.

This feeling had gradually become less and less during the blood-letting, and with its entire removal he found that he had recovered his power of articulating. — PATZE, in *Casper's Wochenschrift*, No. 30, 1844.

FRIDAY, NOVEMBER 29, 1844.

SUBSTANCE
OF
CLINICAL LECTURES

DELIVERED BY MR. STANLEY,

*At St. Bartholomew's Hospital, during the
Summer Session, 1844.*

THERE are at the present time, in my accident wards, twenty-one cases of fracture, and three of dislocation, out of which I shall select some points for consideration, respecting the diagnosis and treatment of these injuries.

Diagnosis of fracture.—In certain cases wherein the occurrence of fracture is not plainly indicated by the mobility or distortion of the part, or by the existence of crepitus, there is one strongly presumptive sign of it, the attention to which has often helped us in doubtful cases, especially in the instances of fracture of the lower end of the tibia and fibula, also of the head of the tibia; this sign is, an acute tenderness of the periosteum manifested in handling the part, combined with deep-seated oedema from serous effusion into the cellular tissue around the periosteum. An experienced hand and eye will readily distinguish these circumstances characteristic of fracture, from the general swelling and tenderness of the soft parts, the result of simple contusion. A man at the present time in the hospital was admitted shortly after he had slipped down in the street; there was no distortion of the leg, and no yielding or crepitus could anywhere be detected; but such was the acuteness of the pain occasioned by pressure of the lower part of the tibia, with the evidence, besides, of the deep oedematous swelling over this part of the bone, that the fracture of it was suspected; and accordingly the limb was confined in splints. Ten days afterwards, an oblique ridge on the lower and front part of the tibia shewed that the

bone was broken, and that the diagnostic sign of the fracture had been of some value in determining the treatment. Crepitus is frequently but a doubtful sign of fracture, especially in the injuries of bones near their articular ends; here it may be caused by an alteration of the synovia within the sheaths of the surrounding tendons, or within the contiguous joint; and, in injuries of the hip or shoulder, when the displaced head of the femur or humerus lies in contact with a surface of bone beyond the articular cavity, in moving the limb a grating sensation may then be communicated to the fingers, so closely allied to that of fracture, as to be with difficulty distinguishable from it. In the shoulder, for instance, when the head of the humerus is driven between the subscapularis muscle and the scapula, the movements of the arm will communicate to the hand of the surgeon a grating sensation, not distinguishable from the crepitus of fracture. As it concerns the diagnosis of fracture, it must be borne in mind, that by the operation of the force which has broken a bone, its ends may get so firmly impacted together, as not to be separable without violence; hence it has happened that a man with both bones of his leg broken has been able to bear considerable weight on the limb. I had a patient whose tibia and fibula were broken about their middle, by the kick of a horse; yet he contrived, with the help of a stick, to walk from Highgate to the hospital, a distance of between four and five miles. Under circumstances of doubt, assistance in the diagnosis may be obtained by ascertaining in what manner the accident occurred; and here it is to be recollected, that a shock imparted to the distant part of a limb may cause the fracture of the shaft of the femur or tibia. A man had just raised a sheep-hurdle from the ground, and was holding it in his hands, when a gust of wind turned him round with the hurdle; the great toe of his left foot coming against a stone, he immediately felt and heard his leg break;

his wife, and another man standing by, also heard the crack. He was directly brought to the hospital, and the tibia was found broken in two places, transversely through its middle, and obliquely through its lower third. Also, on occasions when it would not be expected, an inordinate or spasmodic action of the muscles surrounding a bone may cause its fracture. A coachman, in descending from his seat, felt a sudden twist in his limb; and from that instant he was unable to bear weight on it; he contrived to reach the ground on his other leg without falling, and was directly brought to the hospital, when there was ascertained to be a fracture of the shaft of the femur, just below the trochanters.

Adjustment of fractures.—For this object, in many instances, nothing more is required than that the limb should be placed in an easy posture; directly this is done, the ends of the bone adjust themselves perfectly well. And I have learned by experience, that when one fair effort, by extension of the limb and manipulation of the broken bone, has failed to effect the adjustment of its ends, there is but little probability of success from a repetition of the same proceedings, to which the obvious objections are, the severe pain they occasion, and the injury they do to the surrounding soft parts. When one well-directed effort by extension of the limb and manipulation of the broken bone has failed to effect its adjustment, we must trust to the chance of its adjusting itself; and if it does not do so, we may assume the existence of one or other of the following obstacles to adjustment, over which extension of the limb, or other proceeding we may adopt, can have but little influence,—that the displaced ends of the bone have become firmly impacted together; or that the bone having been broken in two places, and the middle piece displaced, upon which the extension of the limb has no effect; or that a displaced tendon or muscle has got between the ends of the bone; or that one end of the bone has been driven into, and has become firmly impacted in the substance of an adjacent muscle; or that the muscles on one side of the limb having been lacerated, the muscles on the opposite side, their antagonists, acting inordinately upon the broken bone, have displaced it. Of these occurrences the following are examples, mostly of recent occurrence in the hospital.

Fractured ends of the bone impacted together the obstacle to adjustment.—A man suffered a fracture in the middle of his tibia. The ends of the bone projected forwards to the extent of forming an obtuse angle; and they were so firmly fixed in this position, that repeated and forcible extension of the limb, combined with firm pressure against the broken bone, had not the slightest effect

on it. Its ends were necessarily left projecting, and union of the fracture took place in the usual time, but with an awkward-looking bump on the front of the leg. Here the obstacle to adjustment could have been none other than that the ends of the bone were firmly impacted together; and I am sure they could not have been separated by justifiable force. It may be also well to remark, that this peculiar condition of a simple fracture of the tibia occurred in a man 40 years of age, from slipping down on his side, without direct violence to the leg, and that the fibula was uninjured.

A man, aged 74, was admitted with a simple fracture of the tibia, a little above the ankle, produced by the passage of a cart wheel over the limb. An inch above the malleolus internus the edge of the upper portion of the tibia projected, and the skin was tightly stretched over it. Many ineffectual attempts were made to restore the bone into its place. On the seventh day he was attacked by delirium, and on the tenth day he died. On examining the limb, I found a fracture extending obliquely through the shaft of the tibia, an inch and a half above the ankle; also through the malleolus internus, and through the shaft of the fibula. Even after the lines of fracture were brought into view by the reflection of the soft parts, not without considerable force could the bones be adjusted, on account of the firmness with which their fractured surfaces were impacted together.

Fracture of a bone in two places the obstacle to adjustment.—A man in a state of intoxication was kicked out of a public-house, and directly afterwards brought to the hospital with a fracture of the tibia and fibula, and the soft parts around were severely contused from the blows they had received; the consequences of which were, extensive ecchymoses, vesications, suppuration through the subcutaneous cellular tissue, and sloughing of the integuments over the fracture. The end of the upper portion of the tibia projected, with considerable shortening of the limb. Repeated efforts were made to obtain a better adjustment of the fracture, but to no purpose. The projecting end of the tibia was necessarily left sticking in the soft parts on the inside of the leg, for from this position it could not be stirred. The man died under circumstances which will be hereafter noticed; and on examining the limb, the tibia was found fractured in two places, about two inches above the ankle, and at the junction of its upper and middle third. The middle piece of bone, about six inches long, was also split vertically; its upper end projecting against the superior portion of the tibia, prevented this falling into its place. It was evident that no extension, or other manipulation of the

limb, could have effected the adjustment of this fracture.

Displacement of a tendon or muscle the obstacle to adjustment.—Such occurrence is most likely to happen in cases of fracture of the lower end of the tibia and fibula, with dislocation of the ankle-joint. In the examination of one of these cases, in which many attempts had been ineffectually made to reduce the dislocation, the tendons of the tibialis posticus and flexor longus digitorum were found firmly locked between the tibia and fibula, and had thereby prevented the replacement of the articular end of the tibia in its right situation.

End of the bone impacted in the substance of an adjacent muscle the obstacle to adjustment.—This occurrence was strikingly presented to my notice many years ago, in two cases under the care of Mr. Abernethy, wherein the shaft of the humerus had been fractured at about the junction of its upper and middle third, and the end of the lower portion of the bone was driven through the deltoid muscle and skin covering it. No forcible attempt was made to withdraw the end of the bone from the substance of the muscle, in which it was firmly impacted. The result of each case was, that not more than the ordinary amount of irritation ensued; and with the exfoliation of the exposed end of the bone, the fracture united in the usual period, and without deformity. The harmlessness of the end of a bone sticking in the substance of muscle, and the little interference of such occurrence with the reparative processes, were well shewn in these cases. Under such circumstances there must have been either the absorption of the muscle intervening between the two portions of bone, or the gradual loosening and withdrawing of the end of the bone from the muscle into which it had been driven.

A few months ago I had in the hospital a boy nine years of age, who had suffered a complicate fracture of the lower part of the femur. The knee-joint became, in consequence, fixed in the extended position, and the end of the shaft of the femur was found projecting in the lower and outer part of the ham. Repeated and powerful efforts by extension, and various movements of the limb, were made to replace the projecting end of the bone in its right situation, and to restore the motions of the knee-joint; but these efforts were of no avail. The injured parts became firmly consolidated; and when the thickening around them had disappeared, it became evident that there had been a transverse fracture of the femur, just above the condyles, and a vertical fracture between them; and that the end of the shaft of the bone had been driven through the biceps muscle. Ultimately the limb became

firm, and the knee-joint regained a considerable degree of motion.

The foregoing is a good example of a class of cases of complicate fracture, wherein the utmost efforts to replace the parts in their natural position are of no avail, and consequently we have but to await the natural processes of reparation: nor can I omit the remark so frequently suggested by the progress and result of these cases, that when the mischief has not been aggravated by undue surgical interference, they turn out so much more favourably than was anticipated from the formidable character which the injury on its first view presented.

There is always, as it has appeared to me, an interest in knowing the method of occurrence of a complicate injury. In the case just related, the fracture with displacement of the lower part of the femur occurred to a boy in falling from a cart, between the rails of which, his foot being caught, his body became suspended by it; there were no marks of direct violence to the knee, and accordingly it was assumed that the injury had been produced by the twist which the limb received on his body being suspended by it. An increased breadth of the joint, and the loss of the natural prominence of the patella, were the consequences of the vertical fracture between the condyles, permitting their separation and the sinking of the patella between them; there was also a considerable hollow in the front of the thigh just above the condyles, the consequence of the transverse fracture of the femur and displacement of the end of the bone. By the side of the foregoing case the following extract from the *Archives Gén. de Méd.* vol. ix. p. 267, will be regarded with interest. A boy, aged 11, twisted his leg in a hole in such a manner that whilst his body turned round, his leg was fixed. The femur was thus separated from the condyles, and the end of the shaft projected into the popliteal space. On the twenty-fourth day, the leg was amputated on account of mortification of the foot, and on examining the limb, the condyles were found separated and placed so that their articular surfaces were directed forwards.

Inordinate action of the muscles on one side of the limb consequent on the laceration of those of the opposite side, their antagonists, displacing the fractured bone, and constituting an insuperable obstacle to its adjustment.

Of this, the following well-marked instance occurred in the hospital during the last winter. A boy, aged 10 years, was admitted with a compound fracture of both bones of the leg, from a heavy stone falling on it, the edge of which completely cut through the skin and muscles on the front and outside of

the limb. The end of the upper portion of the tibia protruded through the gap in the integuments, and many efforts were ineffectually made to replace it. I removed the pointed extremity of the bone, and then repeated the efforts to replace it, but with no better result; the end of the upper portion of the tibia still projected in front of the lower portion to the extent of full three quarters of an inch. The reparation of the injury was now wholly left to the natural processes; the results were, that with a small exfoliation from the exposed end of the tibia, the bone gradually adjusted itself, and the fracture united without irregularity or shortening of the limb. Here I believe the obstacle to the adjustment of the bone was the uncontrolled action of the muscles in the back of the leg, their antagonists, the muscles in the front and outside of the leg having been completely divided by the sharp edge of the stone.

Treatment of fractures which are slow of union. On the use of the immoveable apparatus.

I select these points for consideration in the treatment of fractures, because it happens that they can be practically illustrated by cases which are, or recently were, in the hospital. There are fractures which are slow of union, and fractures which will not unite; fortunately the former are of most frequent occurrence; they require the help of good apparatus, and it is to the nature of this apparatus, and to the principles which should guide its use, that I am about to advert. Formerly, and indeed until within a few years of the present time, no other view was generally adopted respecting the treatment of fractures slow of union than that if at the expiration of the ordinary period, the union was ascertained to have failed, the splints were re-applied, and the patient again confined to bed, with a more strict enjoinder of the absolute quietude of the broken bone, and that if after the lapse of many more weeks no advance towards the union could be ascertained, it was pronounced an ununited fracture, remediable only by sawing off the ends of the bone, or by the passage of a seton between them, or by some other of the measures appropriated to this class of cases. But we have now learned by experience that in the event of a fracture failing to unite within the usual period, methods are to be adopted far more gentle, and, what is more important, far more likely to be successful, than any one of the severer proceedings just indicated. These methods are, exercise of the limb for the advantage of the action of the muscles surrounding the broken bone, maintenance of firm pressure against the portions of bone, that they may be kept

steadily in contact, and if possible by their periosteal surfaces.

Influence of the action of the muscles around the slowly uniting fracture.

Of this there can be no doubt; it is evidenced to us in the many instances of fracture of the tibia not firmly united within the ordinary period, wherein the patient has been desired to move about on crutches, not bearing weight on the limb, but swinging it about freely, and in a short time the uniting medium, which was flexible, is found to be perfectly firm. I lately had in the hospital a woman, aged 32, with a fracture of the femur, at the junction of its upper and middle third; it was treated strictly by confinement on the back, with the application of a long splint to the outer side of the limb. At the expiration of two months, the ends of the bone were ascertained to be freely moveable. The thigh was then kept firmly encased in leather splints through the next two months, at the expiration of which the ends of the bone were found to be still freely moveable; it was now determined again to apply the leather splints in a manner to maintain firm pressure against the end of the bone, and besides, to encase the thigh in the splints composed of layers of linen cemented together by the mixture of white of egg and flour, and around these to apply the starched roller. The limb being thus secured, the patient was desired to move about freely on crutches. Almost from the commencement of this plan, the woman began to express a consciousness of firmness in the limb of which she had not before been sensible. After another six weeks, the bone had become so firm that she could bear weight upon it, and she left the hospital walking perfectly well. I could draw no other conclusion from this case than that the firm union of the fracture was mainly attributable to the adoption of the proceedings having for their object the free action of the surrounding muscles. Since, in this case, the firmness of union had not commenced at the expiration of four months from the occurrence of the fracture, it almost warrants the conclusion that no period is too late for the commencement of that stage of the reparative process of fracture upon which the firmness of its union depends.

Influence of pressure upon the ununited fracture.—The application to the limb of stiff leather splints, or other apparatus calculated to maintain firm pressure against the bone, is undoubtedly a most important part of the treatment of ununited fractures, and the merit of first establishing it belongs to Mr. Amesbury*. It should not be the object to

* Remarks on the Nature and Treatment of Fractures, Vol. 2.

maintain the fractured ends of the bone in contact, but rather that the two portions of the bone should overlap, to allow of their periosteal surfaces being firmly pressed together, for as the tissue of periosteum is more readily disposed to the deposit of osseous matter than the tissue of bone, accordingly by the actual and firm contact of the periosteal surfaces the advantage is obtained of a better chance of the union of the fracture, which well compensates for the shortening of the limb consequent on the overlapping of the two portions of the bone.

On the use of the Immoveable Apparatus.—The treatment of fractures by the immoveable apparatus, as it is termed, has been of late especially adopted by Dr. Scutin, Chief Surgeon of the Hospital at Brussels. The object aimed at by this treatment is to avoid the inconvenience of confinement, by enclosing the limb in an apparatus sufficiently strong to prevent the separation of the fractured surfaces, and of sufficient lightness to allow the limb to be moved about with ease. Varieties of apparatus have been recommended for this object; that which I employ in the hospital consists of the splints, composed of layers of linen, cemented together by a mixture of white of egg and flour, and of the starched roller. The excellence of the splints thus constructed is, that with the firmness of the case they form, they are so exactly moulded to the inequalities of the limb, that when confined to it by the turns of the roller, not the least movement of the limb within the splints can occur; and this is obviously essential to the quietness of the ends of the bone. Curiously enough this turns out to be the revival of a practice adopted in bygone times. Cheselden, in his *Anatomy*, states "that a professed bone-setter living in Westminster communicated to him the following method of treating fractures; this way was, after putting the limb in a proper posture, to wrap it up in rags, dipped in whites of eggs, mixed with wheat flour; this drying, grew stiff, and kept the limb in good position;" and in his observations appended to *Le Dran's Surgery*, Cheselden observes, "there is no bandage equal to this for a fractured leg. I always use it, leaving that part upon the tibia very thin, that if it grows loose by the abatement of swelling, I then cut out a piece, and bind it closer. Upon a journey, I once set the cubital bones of a gentleman's arm that was broken, and making use of this bandage, he the next two days made long journeys without any inconvenience, and at the end of forty days took it off, and was perfectly well."

There are objections to the indiscriminate use of the immoveable apparatus, and especially to its application upon a fractured

limb immediately after the receipt of the injury; still, however, under certain circumstances, it is a most valuable addition to our plan for the management of fractures. Upon the subsidence of the inflammation and swelling immediately consequent on a fracture, the limb may in general with safety be enclosed in such splints as I have described, and which, when properly applied, will prevent any motion between the ends of the bone, and with a fracture of the femur as of the tibia, by the application of these splints, the patient will be enabled to move about on crutches, and even bear weight on the limb long before the fracture is firmly united. In several cases of fracture of the tibia I have by means of this apparatus been enabled to discharge the patient within little more than a fortnight from the occurrence of the accident, when, for particular reasons, it has been an object of importance to leave the hospital at this early period, instead of remaining here the usual time of five or six weeks. Recently there were in the same ward two cases of simple fracture of the leg, to which this view of the subject especially applies; they occurred in women who were oppressed by anxiety to return home to the care of their families; one was a fracture of the tibia and fibula, near the ankle-joint; and on the seventeenth day, the limb being encased in the immoveable apparatus, she left the hospital, bearing weight on it, and moving about comfortably with the help of crutches; the other was a fracture of the tibia alone, through its centre, and on the nineteenth day, with the same apparatus applied to the limb, she left the hospital, moving about without uneasiness. In another class of cases the greatest benefit has been derived from the use of the immoveable apparatus. I allude to fractures of the thigh and leg in aged persons, in whom, from their not bearing confinement well, the stomach has become deranged, with failure of appetite, and obvious decline of the vital powers; directly these changes are noticed, the injured limb is enclosed in the immoveable apparatus, whereby the patient is enabled at once to get up and move about on crutches, and the unfavourable symptoms have immediately disappeared. I feel certain that by adopting this line of conduct the lives of some old people have been saved, who otherwise would have sunk. Such were the circumstances of the following case. A woman, aged sixty-four, was admitted with a comminuted fracture of the tibia and fibula. When she had been confined upon her back for a week, the skin upon the sacrum became red and painful; it was evident that sloughing of the parts would here quickly ensue if pressure were continued upon them; consequently, I had the patient

placed on her side, but the skin upon the trochanter soon suffered in the same way ; at the same time, the appetite failed, and from the rapid decline of the vital powers, it soon became evident that to confine the patient any longer in bed would certainly be fatal. Accordingly, on the tenth day, I had the leg enclosed in the splints composed of layers of linen, cemented together by the mixture of white-of-egg and flour, thus enabling the woman at once to sit upright in bed, with her legs resting on the floor, and in a few days to move about on crutches. The most marked improvement, in every respect, immediately followed this change in the treatment. The leg, which before the application of the immoveable apparatus was severely painful, now became perfectly easy ; her nights had been restless, but she now slept soundly ; appetite returned, and her vital powers quickly rallied. As the limb continued free from pain, the splints were not removed for a fortnight ; then they were re-applied. At the end of six weeks, the woman left the hospital with the bones in good position, and the fractures firmly united. This woman certainly owed her life to the help that was obtained in the management of her case by the application of the immoveable apparatus to her leg.

The following cases are further illustrations of this treatment of fractures slow of union.

A man, aged 46, was admitted with a very oblique fracture of the tibia and fibula a little above their centre. After strict confinement in bed for seven weeks, with the application of the ordinary splints, not the slightest union of the fracture had taken place. The leg was then firmly encased in leather splints, fixed by strips of adhesive plaster, and surrounded by a starched roller, and he was desired to move about on crutches. When this plan had been in operation about a month, I examined the limb, and found the fracture in progress of union. At the end of another fortnight he could bear weight on the limb ; soon after which he left the hospital with his leg perfectly firm.

A man, aged 66, was admitted with a fracture of the femur about its centre, from a fall into a saw-pit. The limb was strictly confined for six weeks in the straight position, with the long splint applied to its outer side, and through this period the limb had not been once disturbed ; but on removing the splint there was not the slightest union of the fracture. The limb was then treated in the same way for another month, at the expiration of which, the ends of the bone were found to be still freely moveable. The thigh was then encased in leathern splints, bound very firmly to it by strips of adhesive plaster, and the whole surrounded

by the starched roller. At the same time, the man was urged to move about on crutches, which, after a little time, he accomplished. About once a fortnight, the leather splints were removed and replaced, and with the satisfaction of finding the ends of the bone gradually less moveable ; but it was not until five months had elapsed that the uniting medium had become firm enough to support the weight of the body ; this, however, it ultimately did, without yielding, and without pain.

IMPORT OF THE NERVOUS SYSTEM IN SECRETION AND IN IRRITABILITY.

To the Editor of the Medical Gazette.

SIR,

As the due performance of the whole secretory function constitutes health, it must be some failure in this process which induces disease. We may examine every variety of secretion with all the aid and appliances of modern chemistry, and determine their composition with great accuracy, and yet remain entirely ignorant of the mysterious agency by which such wonders are effected ; therefore, although we may know precisely in what health consists, we shall never be able to comprehend why it fails until we have discovered on what it depends. It is thus clear, that the first object of inquiry, without regard to whether one department of the secretory process is more immediately important to life than another, is, simply, what is it that maintains health, or life ? (I consider these terms as being in one sense nearly synonymous ; because life becomes languid, or ceases altogether, in proportion to the failure of one or more of the several parts of the secretory process.) Formerly the term secretory function embraced only the more obvious products resulting from the circulation of the blood ; such as the growth of parts, and of the nails and hair, the deposition of fat, formation of bile, synovia, &c. ; but of late years a more extended meaning has been attached to it, and it is now understood as comprehending every thing eliminated from the blood as it passes through the capillaries whether of the general or pulmonary circulation ; so that now, besides what have just been enumerated, the expression includes the process by which the

blood is changed from black to red, and from red to black, the evolution of caloric, and that constant interstitial change of the elementary molecules in every part, bone, sinew, muscle, and parenchyma of every description, whereby every structure, hard or soft, unyielding or elastic, is maintained in that condition which is expressed by the word healthy. A failure in any department of this function will induce a local disease; and it might be considered that the most simple and easy plan of proceeding would be to take the examination separately of the mode in which each part is affected first, and afterwards to contemplate the whole under similar circumstances. But, in truth, a failure in one part so affects not only others, but the whole, according to the degree of its affection and its subservience to life, that that which is at first simple becomes in its progress excessively complicated; it is, therefore, practically more simple, to regard the failure of the secernent function as a whole, and a clearer and more concise idea of disease will be obtained.

The obvious part which the circulation of the blood plays in carrying the pabulum from which all the various products of the secernent function are eliminated in the different tissues and organs to which it is distributed, has caused the heart and blood-vessels to be regarded as the system on which the maintenance of life more especially depends. It was easy to show that the death of a part was as surely effected by cutting off its supply of blood, as the death of the whole body was produced by draining off the whole quantity of blood; and these circumstances, considered in connection with the fact that the heart may be seen contracting after it has been taken out of the chest and placed in warm water, or even on a table, have been held sufficient by many physiologists to prove, that the sanguiferous system is capable of maintaining the circulation of the blood, and consequently the life, in virtue of its own inherent power or irritability.

Although there appears to be much in the circumstances just mentioned to support this opinion, there are many striking phenomena referrible to the nervous system, which discover in it an influence at least equal to that of the sanguiferous system in maintaining

life; thus we find that a section of the nerves or brain is no less surely followed by partial or total death, than a corresponding injury to the blood-vessels or heart; while it is urged effectively against the idea of the inherent and independent irritability of the heart, that (regard being had to the state of our knowledge, or rather ignorance, of the nervous function, the subtle and mysterious nature of the nervous influence, and how it may be conveyed and distributed to the muscular fibre) it is quite impossible, in cutting out the heart from its connection with the body, to say that it can thus be separated from its nervous influence.

Thus there are two opinions on this most important question so much in opposition, that one of them must be wrong; the former is that which appears to be most in favour with the systematic writers of the present day; to such an extent, indeed, that I do not think Dr. Alison exaggerates, when, in introducing a notice of some experiments performed a few years ago by Dr. J. Reid to the British Association, he says, "Although physiologists are still divided in opinion as to the question whether nerves furnish a condition necessary to the irritation of muscles, (that is, whether every stimulus which excites a muscle to contraction, acts on it through the intervention of nervous filaments), they have now very generally abandoned the once prevalent theory, that the irritability of muscles is derived from the brain or spinal cord." It seems to me, that the great fact, which has above all others operated in turning the current of public opinion in this direction, is the circumstance of infants being born alive without any brain, but perfect in every other respect. This fact has been eagerly seized upon by the disciples of Haller, as affording the exact evidence requisite to place their doctrine beyond the reach of any farther cavil. They argue, that if a fœtus can grow to full size, and be born alive, and move without a brain, there can be no longer any doubt about this organ being non-essential to life, and therefore as little concerned with the secernent function as in supplying any condition necessary to the action of muscles. The birth of these brainless creatures may be regarded as experiments of nature's own performance, of the most unex-

ceptionable kind, uncomplicated with pain, or loss of blood, or shock to the general system, and therefore entitled to higher consideration than any in which the knife is employed. It is very remarkable, that the attention of physiologists has been exclusively fixed upon the fact of these creatures being born alive, while the fact of their death, which invariably soon follows, has been passed over as scarcely worthy of notice; but it is evidently most unfair to lay all the stress on one half of an experiment, and to slur over the other half in silence, where every part is equally profitable for information. An acephalous fœtus may certainly come into the world alive, but we find that it *begins* to die as soon as it is born. The death, therefore, is as much to be considered as the birth; the experiment not being complete until death has taken place. It does not require any great depth of physiological knowledge to enable us to arrive at a just estimate of extent of information which such malformations afford; a little common sense is all that is necessary to a right understanding of the question. Connection with the parent is all-sufficient to maintain the life and growth of a fœtus; but this connection cannot last for ever; the time for separation must come, and it will then require to be furnished with the means of maintaining for itself an independent existence, to compensate for what it will lose when its life can be no longer derived from its original source; if it be not so provided, it must inevitably die. The real question, therefore, is not whether an acephalous fœtus can live and grow in utero, but whether it can live after it has been born; and when we see that infants of this kind invariably begin to die the moment their connection with their mothers is interrupted, bearing in mind the fatal consequences of any serious lesion of the nervous system, and the extent to which all the vital functions are affected by circumstances and events which act on the brain through the mind, I think there can be no other conclusion than that the nervous system maintains the life and growth, and consequently the health, and every manifestation of life. According to this view, an acephalous fœtus is in very much the same situation as any other part which might be cut off from

a living animal, and which dies simply because it has no capability of supporting an independent existence. I consider the evidence afforded by these experiments of nature's own making so conclusive against the doctrines of irritability, that it is unnecessary to bring any formal objections against those of Dr. J. Reid. It is useless to keep up a warfare with pistols, when the citadel is not only taken, but the cannon turned against its former masters.

It is very certain that many of the most respectable of modern writers have ranged themselves among the disciples of Haller; but I think a sufficient reason may be found to account for this, without taking it for granted that the weight of evidence must necessarily rest with the greatest number of witnesses. Those who have adopted the opinion that life is maintained by the agency of the nervous system, have laboured under the great disadvantage of not being able to give such an explanation of its *modus operandi* as might suffice to found a system upon: they have not been able to say what nervous influence is, or how it may be applied, or any thing about it; hence their doctrines have had a certain air of mystification and uncertainty not at all calculated to suit those who have wanted to write books. On the other hand, their opponents, if in error, have at any rate had the advantage of being able to form a clear and connected theory to countenance their practice. They have found in the endowment of the muscular fibre of the heart with irritability an ultimate fact, as a foundation to commence with. This point being gained, they have been able to attribute muscularity and irritability to the blood-vessels, and to find, in experiments which, *under favourable circumstances*, show that a gradual constriction and as gradual a relaxation, rather of the tissues which contain the capillaries than of the capillaries themselves, occupying altogether as much as six or seven minutes, and which may sometimes be repeated as many as nine times in an hour, evidence of their being able to act several thousand times in every hour. This second difficulty being thus surmounted, they have found no trouble in imagining each vessel to be endowed also with the knowledge how to make use of its

power for the common weal of the body, and to meet any emergency that might arise. It appears to me that it is this facility of explaining the various phenomena of health and disease in a plausible manner, rather than their truth, has rendered the doctrines of Haller so acceptable to systematic writers.—I propose to proceed with this subject in my next letter; in the meantime I am, sir,

Your obedient servant,

J. W. EARLE.

Cheltenham, Oct. 1844.

ON PERICARDITIS.

BRIEF OBSERVATIONS, WITH A CASE READ
AT THE FIRST MEETING OF THE SOUTH
LONDON MEDICAL SOCIETY,

Oct. 17th, 1844.

By H. M. HUGHES, M. D.

Assistant Physician to Guy's Hospital.

(For the *London Medical Gazette*.)

It is probable that in no disease has there been within the present century so great an advance in precision of diagnosis, as in Pericarditis. The consequent knowledge of the indications of treatment may be presumed to have made an equally rapid progress. Forty years ago it was scarcely known as a common attendant upon rheumatism, and within the last twenty years it was regarded as one of the most obscure and difficult of detection in the entire catalogue of diseases. Its diagnosis now generally presents no greater difficulty than that of pleurisy. The increased precision which now exists has had its origin almost entirely in the employment of auscultation and percussion, conjoined with the study of morbid anatomy; yet it is remarkable, that almost all the discoveries in reference to the physical indications of this complaint, have been made since the publication of the original work of Laennec, and that most of them have become known, or generally established, since his death. It has been said by one whom all who know respect, that "It is a duty incumbent on the physician, who has ventured at any time to lay before the profession his ideas of disease, and its treatment, to review from time to time his published opinions, that he may see how far subsequent

experience has borne out, or modified, his former impressions; and if he detect any material alteration in his mode of viewing disease, more particularly as regards the practice he has found beneficial, it is right that he should take an opportunity to make it known." In the spirit of this remark, I have recently perused an essay "On the Symptoms and Diagnosis of Pericarditis," written by myself nine years ago, and published in the first number of the *Guy's Hospital Reports*. I find therein many forms of expression which it would be well to change, and some opinions which might be advantageously modified. But considering the time at which it was written, when the author was comparatively young and inexperienced, and when a familiar acquaintance with the disease may be said to have been young also, there is perhaps less to correct than might have been expected, and certainly less than I had myself anticipated. Some points requiring modification may be noticed in the sequel. The distinction, however, there made in three classes of cases of pericarditis; viz. 1st, Those in which pus is effused into the pericardium, and the heart itself is involved as well as its investing membrane, and in which the symptoms are those of acute fever, and are principally referred to the brain; 2ndly, Those in which the effusion is liquid, and large in quantity, from an early period, or from the commencement of the attack; and 3dly, Those in which the effusion is primarily and principally plastic, I still regard as a natural, and therefore a legitimate distinction. Cases of the first order are comparatively rare; those of the second do not occur frequently; while those of the third order are very common. The time which I may consider as fairly allotted to me on the present occasion will not allow of the perusal of an extended essay. I trust, therefore, I shall be excused for expressing myself with a brevity which will almost necessarily give to my statements somewhat of a dogmatical character.

The exciting causes of idiopathic pericarditis may be considered similar to those giving rise to inflammation in other serous membranes—as cold, external violence, the presence of tubercles, extension of disease from contiguous structures, &c. &c. The most com-

mon cause of pericarditis, however, is undoubtedly the state of the system, or circulating fluid, which exists in rheumatism. It has been supposed by some, that in rheumatic pericarditis a true metastasis occurs. If by this it is intended that upon the supervention of inflammation in the pericardium, the rheumatism of the joints altogether, and universally ceases, and that the latter re-appears upon the cessation of the former, the opinion is certainly incorrect; as it often happens that the joints continue to be severely affected during the progress of the internal inflammation. It is nevertheless undoubtedly true that the intensity of the external disease is sometimes considerably diminished upon the supervention of the more severe internal affection. It has been supposed also, that the employment of venesection in acute rheumatism contributes to the production of pericarditis. There may be some truth in this opinion. It is certainly, to say the least, a remarkable coincidence, that when M. Bouillaud commenced the practice of repeated bleedings ("his *saignées coup sur coup*") for the cure of rheumatism, he then, and not till then, discovered (years after the fact was generally known in England,) that the disease was very frequently, or he says himself almost always, accompanied with some affection of the heart. It is indeed possible, that by his frequent venesection, M. Bouillaud may have contributed to the production of anæmic murmurs, which may have been sometimes regarded as an indication of the presence of endocarditis; but it is also possible that the same cause may have contributed to the production of disease in the heart, or its investing membrane. On the other hand, many years ago I was in the habit of seeing a good deal of the practice of an experienced physician, whose almost universal habit it was to prescribe venesection in acute rheumatism, yet I certainly do not remember to have observed that his patients were more frequently attacked with pericarditis than those of his colleagues, who treated differently the patients submitted to their care. It has been lately asserted that pericarditis in rheumatism is caused by the administration of colchicum, and that it rarely, if ever, occurs when that medicine has not been employed. This is certainly a mistake;

though when the remedy acts violently, and depresses greatly the power of the patient, it is possible, that, like venesection, by causing the complaint to shift its seat without removing its cause, it may, in persons predisposed, rather favour the occurrence of the internal complaint.

Pericarditis may appear during every stage and in every form of rheumatism. It more commonly, however, occurs during the first ten, or perhaps six days of its course, and in the acute or sub-acute form of the disease. It is also, I believe, more frequent when the original affection is constantly changing its seat, attacking this joint to-day, and that joint, or set of joints, to-morrow. It is certainly much more common in children than in adults, and, as a general rule, I believe it may be stated that the younger the subject affected with rheumatism, the more liable is he to inflammation about the heart; and conversely, that the older the patient is, the more likely is he, supposing him to have been previously free from cardiac disease, to escape this important complication. When first attacked with pericarditis, the patient often makes no complaint in addition to those which had been before noticed, but the observant practitioner generally at once sees that he is not so well, and that there is increased mischief somewhere. He remarks that the aspect is altered; the position of the body more constrained; that the pulse has changed in character, and has become less tense, and more frequent; that the skin, if not dry, is less profusely covered with perspiration; and upon inquiry, but often only upon inquiry, he finds that his patient has a sense of oppression, or a dull heavy pain, at the scrobiculus cordis. His attention being now directed to the heart, he ascertains that tenderness exists upon pressure in the epigastrium, or in the intercostal spaces over the heart; that the diaphragm is very slightly depressed in the act of inspiration, and that the respiration is therefore nearly entirely thoracic. Upon applying the ear, or stethoscope, to the chest, nothing abnormal may be at first discovered; but, if not at that time, on the next day, there will be heard a superficial rubbing noise in some portion of the præcordial region, and very frequently, together with this, a bellows

murmur in the situation of the aortic valves. Such, then, are commonly the indications of the existence of pericarditis: a pinched or anxious countenance, approaching to the "risus sardonius;" a constrained position of the body, with great disinclination to move it; a pulse varying from 96 to 120, less tense and thrilling than that of uncomplicated acute rheumatism, but of variable character; the skin less inclined to profuse perspiration; the respiration effected by the elevation of the ribs, without descent of the diaphragm, (a condition exactly opposite to what occurs in common pleurisy, but similar to what happens in that disease, and in peritonitis, when affecting the diaphragm,) oppression or pain at the base of the sternum, and frequently tenderness upon pressure of the præcordial region*.

As the disease advances, and the effusion is therefore more extensive, the rubbing noise becomes more distinct and generally diffused; the other symptoms continue, or increase in violence. If the patient is early seen, and is of good constitution, the disease is speedily recognised, and, actively treated, the rubbing noise ceases almost as suddenly as it appeared; no appreciable dulness on percussion will be discovered, and the other symptoms rapidly vanish. If, on the contrary, the patient is of an unhealthy habit of body, scrofulous, or phthisical, or depressed in power, is not seen soon after the accession of the complaint, or is not treated efficiently, the rubbing may also suddenly disappear; but from an entirely different cause; serum, or seropurulent fluid is effused, and being interposed between the two layers of the roughened pericardium, interferes with their attrition, and consequently prevents the sound which is produced by it. This cessation of the rubbing noise does not always occur suddenly all over the præcordial region, but sometimes commences from below, and gradually progresses upwards; so that the amount of fluid effused can be determined with tolerable accuracy by the defined line below which the rubbing

cannot be heard, and above which it is still audible. It sometimes happens, after some dulness on percussion has already appeared, that the rubbing noise, which so long as the patient lies quietly on his back cannot be heard, in consequence of the intervening serous effusion, may be reproduced by altering the position of the body—as turning upon the side, or sitting up in bed, by which the serous fluid gravitates from between the opposing surfaces of a portion of the pericardium, and thus allows of their coming in contact, and of their attrition. I have also observed, after the rubbing noise has temporarily ceased, in consequence of a small amount of serous effusion, if the patient is young, and the ribs therefore freely flexible, that even while he is lying upon his back, the rubbing noise, which is inaudible under ordinary pressure, may sometimes be reproduced by pressing the stethoscope, or ear, more firmly than usual upon the præcordial region. This arises from the local pressure squeezing out the fluid intervening between those portions of the pericardium to which the stethoscope is applied, and thereby causing the two roughened surfaces again to rub against each other. The rubbing noise at length disappears altogether, and at or about the same time the natural dulness of the præcordial region is increased both in extent and in degree: the patient becomes more distressed, the countenance more anxious, the breathing more hurried, the pulse more rapid and feeble, sometimes fluttering and irregular; the natural sounds of the heart are but feebly heard, and no morbid sounds are audible; the action of the heart is tumultuous, the patient is unable to lie down, the face becomes suffused with perspiration, and the heat of the extremities decreases: unless soon relieved, the patient dies, and after death a considerable amount of fluid effusion is found in the pericardium. If, on the contrary, the medicines act favourably, and the remedies employed produce their intended effect, the expression of the countenance improves; the breathing becomes less hurried, the pulse more firm and full, and the rubbing noise is again heard; first, at the upper part, and then gradually, as the fluid becomes absorbed, over the whole of the præcordial region. At the same

* It is not, however, a little remarkable, that Dr. Addison, who does not dispute that pain may occur as a symptom of pericarditis, has never, to his knowledge, met with a case where he had an opportunity of arriving at a positive conclusion, either from inspection or stethoscopic signs, that he did not find pleurisy conjoined.

time, but by no means with equal rapidity, the dulness on percussion diminishes. It generally happens that after a few days the rubbing again partially or entirely disappears, in consequence either of the adhesion of the pericardium, or of the complete removal of the inflammatory effusion. In a short time the patient regains his strength, and feels and represents himself well. He is, however, too often left with a damaged heart from some product of disease remaining behind, either internally or externally, and sometimes both. It sometimes happens, on the contrary, and particularly when the disease has been of long continuance, and has existed for a considerable period in a chronic form, that though the fluid be absorbed, the two surfaces of the serous membrane do not adhere, in consequence of a dense coating of organised solid matter of varying and variable density, which itself becomes a secreting surface. Under such circumstances, the individual has for months or years, or sometimes during the whole of his remaining life, a harsh rubbing, grating, or scraping noise, over the whole or a portion of the præcordial region, which is frequently so loud as to be distinctly heard by persons standing near the patient, without applying the ear to the chest, and to be audible by the patient himself. If he be again attacked with pericarditis, fresh effusion may occur, and the two surfaces thereby become permanently adherent.

The rubbing noise ("frottement") of pericarditis has been stated gradually to merge into the bellows murmur, "*bruit de soufflet*," and the late amiable and lamented Dr. Hope supposed that the latter, when occurring in pericarditis, might be caused by the rapid propulsion of the blood through the aortic opening. The former opinion I deem a mistake, the latter a dangerous error.* I do not indeed now believe that the bellows murmur is so constant or almost universal an attendant upon rheumatic peri-

carditis, as when I wrote the essay to which I have referred, yet continued observation leads me to suppose that it is very frequently present, and that even when not detected, it is often for a time only obscured by the more noisy and superficial rubbing noise, produced by the attrition of the roughened pericardium, and therefore that it does not become audible till that rubbing disappears. I am also deeply impressed with the conviction that it arises from inflammatory thickening of the sigmoid, or other valves, and that, frequent as is the occurrence of pericarditis in rheumatism, the inflammatory thickening of the valves (the so-called endocarditis of some authors,) is a much more frequent, and prospectively a much more serious complication of that complaint. With a thickened or adherent pericardium, it appears probable at least that a person may continue to live for many years without much inconvenience. With thickened valves, and consequent obstruction in the cardiac orifices, farther morbid changes almost necessarily commence at once. As it is a more frequent, and prospectively a more important complication of rheumatism, I believe that the internal affection, in consequence of its less prominent symptoms, is also much more liable to be overlooked. It is not generally, however, I believe, strictly speaking, true endocarditis, or inflammation of the lining membrane of the heart, but disease of the tissue behind the lining membrane, which it often leaves as smooth and as polished as before the attack, although the valves themselves may be opaque, thick, and rigid. True endocarditis gives rise to vegetations or plastic effusion upon the lining membrane: this affection generally produces a deposit below the membrane.

The affection I have briefly referred to in the preceding pages is pericarditis, primarily accompanied with plastic effusion, as in a great majority of cases it occurs in connection with rheumatism. When arising independently of this disease, the inflammation of the pericardium is more frequently accompanied in an early stage with fluid effusion. Then, of course, the signs afforded by the attrition of the roughened membrane will be absent. Liquid effusion exists more especially

* Since writing the above, I have been informed by Dr. Munk, that though the late Dr. Hope did hold the opinion stated in the text, at the time his work was written, he had occasion to change his views upon the subject before his death, and believed that the bellows murmur in pericarditis was produced, as I have long maintained, by inflammatory thickening of the valves.

when the disease occurs in scrofulous subjects, or in persons worn down by other chronic disorders, or when it takes place in the last few days of life.

So common is one or other, or both, of the affections to which I have referred as complications of rheumatism, especially in young subjects, and, though little regarded at the time of the attack, so serious are the consequences to the sufferer in after life, that I conceive a practitioner, while attending a patient with acute rheumatism, should at every visit examine the heart, by placing the ear or stethoscope on the præcordial region, that he may discover and repulse the dangerous and insidious enemy on its first appearance.

In reference to diagnosis, the only affections with which pericarditis, when occurring under the inspection of an observant and well-informed practitioner, is likely to be confounded, are pleurisy in that portion of the serous membrane which lies over the heart, and old pericardial disease. The diagnosis between the former complaint and pericarditis is indeed an affair of extreme nicety. In both a rubbing noise may exist synchronously with the systole and diastole of the heart, and if the pleurisy extends, as it often does, to the phrenic portion of the membrane, in both is the respiration thoracic, and the countenance, the breathing, the pulse, may be similar in both. Under such circumstances I know of no distinction between the symptoms and physical signs of the two complaints, excepting that it may be generally observed, that in the pleuritic complaint the rubbing becomes obviously louder during the act of inspiration, by which the roughened pleura is more firmly appressed against the heart, than during the expiration. This may be considered too trifling a circumstance upon which to found a diagnosis; it is therefore fortunate that the treatment of the two diseases is identical. To determine whether an individual who has been attacked with acute rheumatism, who has previously suffered from the same complaint, accompanied with pericarditis, and who is now seen for the first time, has or has not a recent inflammation, supervening upon old disease of the pericardium, I hold to be impossible. It is therefore, I think, the safer practice

always to treat such patients as if recent disease actually existed.

Mercury, together with the vigorous employment of local bleeding, and counter-irritation, may be considered as the great remedy in pericarditis. It has been indeed stated by a deservedly high authority, that in salivation alone is safety; in other words, that unless the patient can be brought under the constitutional effect of mercury, the disease, when accompanied with fluid effusion, will prove fatal. It has been also supposed by some, that adhesion of the pericardium is almost the necessary attendant of recovery from an attack of acute pericarditis. As a rule, the truth of both these propositions may be conceded. They are, however, I think I may be allowed to say, liable to exceptions, as persons do occasionally recover who have been known to labour under acute pericarditis, but who have presented no other evidence of the constitutional effects of mercury than the subsidence of the disease; and numerous instances occur in which patients recover, in whom the disease has not been recognised, and has consequently not been submitted to any treatment. It must also, I think, be conceded that after an attack of pericarditis with effusion, a patient may regain a tolerable state of health without adherence of the membrane; that in fact the effusion may be absorbed, and the pericardium restored to its natural condition; unless, indeed, an adherent pericardium may exist for years without causing the slightest distress to its possessor. It is, however, certain that such cases are very rare, and that their very existence may still be doubted. I possess copious notes of a case which I attended in the year 1837, as a patient of the Surrey Dispensary. He took two grains of calomel (with opium and antimony) every four hours for ten days, and in addition thereto rubbed in mercurial ointment three times a day for five days. He continued the same remedies at longer intervals for some days after. The mercury did not run off by the bowels, and indeed appeared to produce no other effect than that of increasing the quantity of urine, yet after rather a tedious illness he so far recovered as to be able to return to his work at a printing-press, at which, with occasional intermissions, he con-

tinued to be engaged for more than a year and a half. He ultimately died, rather more than two years afterwards, under the care of my colleague, Dr. Barlow, with the ordinary symptoms of diseased heart. After death, this organ was found greatly enlarged; the pericardium universally adherent by the intervention of a moderately thick layer of old semi-transparent adventitious matter; the valves, with exception of those of the pulmonary artery, were thickened, and both pleuræ were adherent by recent lymph to the external surface of the pericardium.

I shall conclude by the relation of a single case, the features of the disease in which were especially well marked. I have entered into as little detail as possible, consistently with my object of presenting to the Society a distinct and illustrative example of the complaint on which I have the honour to address them.

CASE. — *Rheumatism.—Old disease of the heart, acute Pericarditis, Diarrhæa, &c.*

J—T—, æt. 14, a delicate looking girl, of light complexion, was admitted into Guy's Hospital under my care, June 8th, 1844. Two years before she had suffered from an attack of acute rheumatism, with some inflammatory affection of the heart, for which she had been actively treated and salivated. In about three weeks she had tolerably recovered, and had not since that time been attacked with rheumatism, or any acute disease, but had been occasionally troubled with shortness of breath, to which she had not been previously liable. Two days before admission, after exposure, she had been again attacked with acute rheumatism, and upon being placed in bed presented in a marked degree the common features of that complaint. The wrists, knees, and ankles, were red, swollen, and tender; the skin was soft and perspiring; the tongue coated with a thick flannel-like fur; the intellect clear; the bowels open; the urine high-coloured, and in small quantity; the pulse about 100, tense, and rather jerking. The præcordial region was found to be natural in both the extent and degree of dulness. The rhythm of the heart was also natural, and its impulse not abnormal; but towards the base of the organ was heard

a diffused and rather indistinct rubbing noise, which was certainly not of the character produced by the effusion of recent lymph, and which it was supposed might not improbably be dependent upon the unabsorbed product of her former attack. Still it was not to be overlooked, and she was consequently ordered to be cupped to ζvj. to the region of the heart, and to take

Pil. Antim. Opiat. c. Cal. gr. j., nocte maneque, et Mist. Magnes. c. Magnes. Sulphat. dimid. quantitate et Vin. Colech. ℥xv. ter die.

She was visited daily, but as no important change took place in her symptoms, excepting that the medicine acted freely on the bowels, the pains of the limbs somewhat decreased and shifted their place, and that what was presumed to be old pericardial rubbing rather diminished, it is not necessary to give any particular report till June 12th, the fourth day of her stay in the hospital, and the seventh of the disease. She had then the peculiar and somewhat anxious expression, and the disinclination to move the trunk, which are so constantly observed in pericarditis; her face was flushed, her skin hot; the pulse was more frequent and less tense; the respiration was pretty purely thoracic; she complained of oppression and weight at the chest; and of tenderness upon pressure over the præcordial region. Below the left nipple was now also very distinctly heard a rubbing noise (frottement) resembling that produced by the friction of two moist and soft, but rough surfaces. The prescription was as follows:—

Appl. C. C. regioni cordis ad ζviij.
Pulv. Rhei. c. Cal. gr. xij. hora scmmi.
Cont. Pil. 6ta quaque hor. cum Haustu Salin.

June 13th.—The powder had acted violently, and the bowels continued to be considerably relaxed; the rubbing noise had extended; *i. e.* it was heard over a considerably larger portion of the præcordial region. The oppression and tenderness upon pressure had been relieved by the cupping.

Omittatur Mistur. Rep. Pil. Capt. pro renata Mist. Cretæ, ζj.

During the next four or five days the rubbing gradually extended, and was at length most distinctly heard over the entire præcordial region. No

dulness, however, could be detected by the amount of percussion of which the tenderness produced, conjointly by the disease and by the previous cupping, permitted the employment. The countenance meanwhile retained its anxiety of expression, and the respiration its thoracic character, and the diarrhœa continued, notwithstanding the employment of the means indicated by the following prescriptions, which I here copy, in preference to giving a perhaps tedious daily report of her symptoms, which varied little during the period in which they were ordered.

14th.—Pulv. Ipecac. C. Hydrarg. c. Creta, aa. gr. iiss. M. ft. Pil. ter die sumend. Mist. Cretæ. post singulas desliquidas.

15th.—Cont. Mist. et Pil. Enema Amyli, c. Tr. Opii, ℥xv. statim injiciend. et cras mane repetend. urgent. diarrhœa.

16th.—Rep. Enem. Mist. et Pil. Empl. Cantharid. regioni cordis, et (in consequence of a slight pleurisy of the right side, indicated by pain and rubbing) applicentur Hirudines v. lateri dextro.

18th.—Omittantur Pilul. sed curetur pars exulcerata Ung. Hydrarg. fortioris, et Capt. c. singulis dosib. Mist. Tr. Opii, ℥iij. 6ta. quæque hora.

On the 19th, a new and a more alarming set of symptoms presented themselves. The gums were not even slightly affected by mercury, which in one or other form had been persisted in for eleven days; the rubbing, so distinct and general up to this day, had entirely disappeared; the præcordial region upon percussion had increased in dulness, both in extent and degree, and appeared also somewhat full and prominent; the countenance was now depressed, and excessively anxious; the face pale, and, together with the rest of the body, covered with perspiration; she could not lie down, and it was consequently necessary to support her with pillows; the respiration was much hurried, 48 in the minute; the pulse small, frequent, and running from 140 to 160 in the minute; the diarrhœa continued, but had now assumed more of a dysenteric character, as she had frequent calls to go to stool, but the evacuations were scanty, consisted chiefly of bloody mucus, with only a slight admixture of dark bilious feculent matter, and were passed with much tenesmus.

Ordered Empl. Cantharid. regioni cordis; Ung. Hydrarg. fort. 3ss. nocte maneque cruribus infricand. Cont. Mist. Cretæ c. Tr. Opii. ut antea. R. Pil. Saponis C. gr. viij. ft. suppositorium statim adhibendum.

20th.—The aspect of the countenance had somewhat improved, and the suppository had had the effect of removing the irritability of the rectum for several hours; in all other respects she was as on the day before.

Pergat. Rept. Suppositor.

21st.—She had improved in every respect: the gums were now fairly affected by the mercury for the first time since her illness; the dysenteric diarrhœa had considerably decreased; the countenance was much less anxious; the breathing less hurried, and the pulse less frequent and more distinct. A slight rubbing noise, synchronous with the systole and diastole of the heart, could not be heard at the upper part of the præcordial region.

Pergat. Beef-tea and arrow-root.

24th.—The rubbing had gradually reappeared over a larger extent of surface from above downward, and was now heard over the greater portion of the pericardium. It was, however, still slight in its intensity, and the dulness on percussion was nearly as extensive as before; the gums were sore; the bowels quiet; the respirations 38, and easy; pulse 120.

Cont. Ung.

R. Potass. Iodidi, gr. iss.; Liq. Potass. ℥xij.; Inf. Aurant. 3iss. ter die.

27th.—She had progressively improved: the bowels were natural. Respirations 40; pulse 120; the tongue was pale, moist, and rather furred from the mercurial action; the pericardial rubbing was now very distinct, loud, and general.

Cont. Mist. et Ung. Applicet. regioni cordis Empl. Cantharid.

She continued the same medicines, with slight and unimportant variations, up to July 1st, when the pulse was still 120, and the respiration, upon slight exertion, 40 in a minute: the pericardial rubbing had entirely disappeared, but a loud bellows murmur was now heard over the situation of the aortic valves; the tongue was moist, still rather furred from the mercury;

the appetite good: the sleep comfortable, and the strength increased.

Ordered—Ext. Hyosciam. gr. v. singulis noctibus sumend.; Sp. Ammon. C. ℥xx.; Inf. Aurant. ʒss. ter die. Intermittatur Unguent. Fish, and in two days a mutton chop.

After staying for a few days longer in the hospital, her mother was anxious to take her home; she was consequently removed to the vicinity of town, and from that time continued tolerably well.

On September 30th, I met her on London Bridge looking plump, and in good health, and walking briskly without any apparent inconvenience.

This case was not remarkable in consequence of presenting any unusual features, but rather from the changes occurring in its progress being uncommonly distinct and well defined, and from its being complicated with a long and severe attack of mucous irritation of the bowels, which undoubtedly placed the life of the patient in great jeopardy for some days. Upon her admission, in addition to the common symptoms of acute rheumatism, there existed evidence of *some* mischief about the heart, which it was supposed had been probably left by her former attack, and was considered to depend upon a roughened state of the pericardium. The distinct superficial rubbing of acute pericarditis, with solid effusion, afterwards appeared; the extension of which could be easily traced by the gradually enlarged surface over which the rubbing noise was audible. Then came the well-marked symptoms of large fluid effusion, together with increased dulness on percussion, and the sudden and complete cessation of the abnormal sound, which, as the fluid became absorbed, reappeared, and gradually extended from above downwards, till it was again heard over the entire præcordial region. It remained audible, until, as it was presumed, the adhesion of the two layers of the pericardium removed the physical conditions upon which it depended. One circumstance only, in connection with the symptoms and physical signs of the complaint in this instance, appears to admit of doubt, viz. the valvular disease indicated by the noisy murmur heard over the sigmoid valves at her exit from the

hospital, in connection with the evidence of old disease upon her admission. Upon this circumstance two explanations may be offered; neither of which appear to be improbable. 1st. We may have been mistaken as to the origin of the sound heard upon her admission, which may have arisen from disease of the valves; as old pericardial disease is not always easily, if, indeed, it can be at all positively distinguished from disease of the valves; or 2dly, the valves may be supposed to have been previously healthy, but by the recent attack to have become thickened and rigid. The indications of this change may have been obscured by the more noisy pericardial rubbing as long as it existed, may not have been elicited while the pericardium was distended and the heart oppressed by the accumulated serous effusion, and may therefore not have become obvious until the causes of their obscurity or their absence had disappeared.

With the exception of the question just mentioned, the diagnosis in this case, particular as well as general, was not doubtful, indeed could not be doubted, by one practically conversant with auscultation. Every variation in the condition of the pericardium appeared almost as distinct and obvious as if it had been actually exposed to view, and the chest, by the aid of auscultation, had been open to the eyes as well as to the ears of the examiner.* The prognosis, even in reference to the existing acute attack, was for several days exceedingly unfavourable, and I was on more than one occasion far from feeling satisfied that at my next visit I should find the patient alive. From this alarming state it appeared evident that she was released by the action of mercury; so soon as it began to affect her constitutionally the more urgent symptoms of her disease became ameliorated. The ultimate prognosis is necessarily unfavourable, as after two severe inflammatory attacks she is left with disease of the valvular apparatus of the heart, as well as of the pericardium. As to the treatment adopted, I have simply to observe, that deeply impressed with the importance of bringing the patient under the influence of mercury, I persisted in its employment, notwithstanding the mucous irritation of the bowels, which it was attempted, though ineffectually,

check by the administration of chalk and opium, and the employment of opiate enemata. I was at length unwillingly compelled, by the exceedingly excited and irritable state of the lower bowels, to suspend the internal use of mercury, and trust solely to its external inunction. The system was soon after affected by the remedy, and was kept under it for a considerable period. As soon as the internal employment of mercury was discontinued, the dysenteric state of the bowels was easily subdued by ordinary remedies, among which opiate suppositories appeared to be the most effective. On this account I am disposed to believe that it might have been more prudent to have desisted from the internal administration, and to have trusted to the external application of the mercury, at an earlier period.

SINGULAR CASE OF FATAL INTRA-UTERINE HÆMORRHAGE.

By WILLIAM THOMPSON,

Surgeon, Bognor.

(*For the London Medical Gazette.*)

Mrs. K., aged about 45, who had previously borne twelve children, and who was then at the end of the ninth month of pregnancy, retired to bed about nine o'clock on the night of the 5th of October, 1844. She had been perfectly well during the day, and, as far as I can ascertain, had felt none of the premonitory symptoms of labour.

About half-past nine o'clock she awoke her husband, and told him that she felt in pain, and must get out of bed; she did so, staggered against a chest of drawers, and fainted. He got her upon the bed, but says that she did not recover consciousness for a quarter of an hour. He wished to send for the midwife, but she said it was of no use to do so, as she had no pains of any consequence.

From this time till six o'clock the next morning I can obtain no very clear account of her state. At that hour the midwife was called, who found her in a very low exhausted state, her pains trifling, and recurring at long intervals. She found the os uteri well dilated, and the presentation natural, the vertex being in the brim of the pelvis.

The poor woman continued to get weaker and weaker for the next two hours; her respiration difficult, and articulation low and indistinct. At last she said she was sure there was something wrong, that she felt as if she was dying, and requested a surgeon to be sent for. On reaching the house, Mr. Peskitt found that she had breathed her last, and observed that she had the blanched appearance of a person who had died of hæmorrhage.

On examination per vaginam he found no discharge of any kind, the membranes entire, os uteri fully dilated, and the head in the brim of the pelvis.

I assisted at a post-mortem examination of the body, about fifty hours after death (up to which time there had been no discharge from the vagina). On opening the abdomen, we found the uterus very large, and apparently filling the whole cavity, pressing the whole of the floating viscera strongly upwards and backwards; these latter had a very bleached appearance, and all their vessels were empty. On raising the fundus of the uterus an immense quantity of bloody fluid rushed from the vagina; and on cutting into the womb (the walls of which were very thin), we found that it still contained more than two quarts of fluid and grumous blood, mixed with large coagula, which completely surrounded the child, enveloped in its membranes entire, with the head in the brim of the pelvis.

The placenta was wholly detached from the uterus, but the place where it had been attached was evident enough, on the right side of the womb, below the fundus: we examined this part very narrowly, but could discover nothing unusual in its appearance, or in that of the placenta. I think there can be no doubt that the hæmorrhage was caused by a partial detachment of the placenta, about the time she first complained of pain and faintness, and that it continued till nearly all the blood in her body was poured into the cavity of the womb. The total detachment of the placenta might have been caused by the immense distension of the womb, and the pressure of such a quantity of blood between its parietes and the membranes.

Bognor, Nov. 12, 1844.

ANALYSES AND NOTICES OF BOOKS.

“L’auteur se tue à allonger ce que le lecteur se tue à abrégé.”—D’ALEMBERT.

An Apology for the Nerves; or, their Influence and Importance in Health and Disease. By SIR GEO. LEFEVRE, M.D. Post 8vo. pp. xii. and 363. Longman and Co.

ANY peg will serve to hang a hat; and any title, it may be said, suffices a clever man to write an amusing book upon. In this “Apology for the Nerves” we have, in fact, a collection of short essays, pleasant, sparkling, full of anecdote, and observation, and learning, upon a very considerable proportion of the ills that waylay mankind; and which if they do not in every instance tend to cut short our journey, still in numerous instances make life a weary pilgrimage, full of bodily, and what is perhaps even worse, of mental suffering. We have the physiology of the brain and nerves discussed; the blood, muscular motion, nutrition and secretion, lightly and pleasantly handled; then we have sympathy, phrenology, mesmerism, sleep, and dreams; then the senses; next the influence of the blood upon the nerves, and such particular subjects as nervous complaints, headaches, epilepsy, palsy, catalepsy, hydrophobia, trismus, delirium tremens, hooping-cough, chorea, cholera morbus, scorbutus, diabetes, and fevers, &c. passed in review, and all with an ease and a grace that make us proud of having one member of the medical profession at least among us, who can blend amusement with instruction, interlard grave discussion with pleasant anecdote, and add general literature by way of seasoning to the tough morsels of pathology and etiology, diagnostics and therapeutics. We bid Sir George Lefevre’s “Apology for the Nerves” welcome! We have already passed more than one pleasant hour in its society, and have found striking illustration of more than one topic that had presented itself in dim perspective to our mind’s eye, among its pages.

As the apologist of the nerves, our author of course gives them enough to do. The nervous influence it is which enables man “to resist a degree of heat

superior to that of boiling water, and without injury.” But “the power is of short duration, the nervous influence is exhausted, and then chemical agency comes into play.” (p. 20.) It is not otherwise with cold:—

“As long as nervous excitement can be kept up, the resistance of cold is very great. General Piroffsky informed me, that in the expedition to Khiva, notwithstanding the intenseness of the cold, the soldiers marched along, singing, with the breasts of their coats open; but only as long as they were flushed with the hopes of success. Where there is nothing to excite, and where exposure to cold takes place under the common routine of parade, its depressing effects are lamentably felt by those long exposed to it. In the time of the Grand Duke Constantine, a regiment of Horse was marched from Strelna to St. Petersburg, a distance of twelve miles and upwards. He marched at their head at a foot pace all the way. He had well wadded himself, and smeared his face over with oil. It was the gratification of a whim to expose the soldiers to a great degree of cold. They arrived at the square before the palace, and were dismissed to their barracks. The following day one-third of the regiment was in the hospital, attacked by nervous fever, of which many died. There was no stimulus of necessity in this case, but the moral feeling aggravated the physical suffering.”

We have quoted this interesting anecdote with a view particularly to the miasmatisists, and to ask them, whence came the malaria that induced the fever in one-third of these men, so wantonly exposed to a temperature probably little short of the freezing point of mercury?

We have tried for another extract upon some point that we conceive would be more particularly interesting or instructive to our readers; but, in truth, we are puzzled. We find the whole book, where Sir George Lefevre relies on himself, and does not quote from Müller, and Magendie, and Legallois, and the rest of the physiologists, alike interesting and, to the general reader instructive; and we can only refer to the whole as to a most pleasant repast. How beautiful is the short disquisition upon sleep! how tasteful that on dreams! how *piquant*, to borrow a

French word, and quietly humorous, that on instinct and reason! Sir George, like all true and kind-hearted men, is a lover of animals, and does not hold them so utterly degraded below the level of humanity as many astute and over-arrogant philosophers:—

"It is difficult," he says, p. 262, "to suppose that animals can dream upon mere instinctive powers; and yet there is no doubt of the fact of their dreaming. Memory is one of their attributes, whether sleeping or waking. The effects of liquors upon the animal's senses are the same as upon the human, though it is only the pig which seems to take pleasure in this species of recreation. The passions are all in full force among them—love, hatred, revenge, jealousy. I once saw a quail that literally died of chagrin.

"If, however, the higher powers of reason be denied to animals, they are not, on the other hand, chargeable with some of its less noble attributes.

"It is doubtful whether they possess that species of sophistry which allows man, under certain circumstances of self-deception, to make evil appear good,—and of necessity a virtue.

"If a dog were caught by the leg in a trap or gin, would he find such means of consoling himself as Hudibras did when his feet were fast in the stocks? It was then, and not till then, perhaps, that the knight understood the value of his spiritual half—the unconfinable part—the free agent:—

"Quoth he,—Th' one half of man, his mind,
Is *sui juris* unconfin'd,
And cannot be laid by the heels,
Whate'er the other moiety feels."

It was by dwelling upon the advantages of one that he lost all feeling of the other, as others have done before him. Here, then, as he himself expresses it, the *rationalia* have advantages over the *animalia*, and pursuing his system still farther, sophistry allowed him to believe that his valour was increased by his defeat.

"The rational faculties of Ralph were of a much less noble order; and mark the difference between the man and the philosopher. His mode of reasoning approaches, or rather hardly soars above that which the dog would have manifested under similar circumstances:—

"Quoth Ralph,—How great I do not know,
We may by being beaten *grow*,
But none that see, how here we sit,
Will judge us *overgrown* with wit."

The sophistry of Hudibras allowed him to glory in his captivity,—his mind soared as his body became debased. Ralph's inferior soul was downcast and mortified,—he regretted the want of that wit or cunning which (had he possessed it) might have preserved him from his disgraceful imprisonment.

"The dog might feel as much in a similar case. We say of animals that they go mad,—that they lose their senses. We say the same of our species, but we say also that they go out of their *minds*.

"This is not said of animals. There seems to be some difference between the two, if we may judge from what language implies. We never say that a man goes out of his soul,—to lose one's soul has a totally different signification.

"Soul implies, therefore, more than mind or senses; and is not the union of mind, sense, and soul, the power which constitutes human reason?"

This will suffice to give our readers a notion of the pleasant vein in which the whole book is composed. It will shew our author as a fluent writer, an apt quoter, and well-read man. Every page gives evidence of kindliness of nature; and wherever he shews himself as the physician, we see the sound practitioner, resting obviously on the sure foundation of science allied to ample experience. Let our readers get the "Apology for the Nerves" forthwith, and judge of it for themselves; if they have not already made the author's acquaintance through "The Life of a Travelling Physician," let them make it now through the no less pleasant channel of the "Apology for the Nerves."

MEDICAL GAZETTE.

Friday, November 29, 1844.

"Licet omnibus, licet etiam mihi, dignitatem
Artis Medice tueri; potestas modo veniendi in
publicum sit, dicendi periculum non recuso."

CICERO.

DISSIMILAR VIEWS OF THE PROPOSED MEDICAL BILL, TAKEN BY METROPOLITAN AND PROVINCIAL PRACTITIONERS.

"This doctrine of tyranny hath taken the deeper root in men's minds, because

the greatest part was ever inclined to adore the golden idol of tyranny in every form, by which means the rabble of mankind, being prejudiced in this particular, and having placed their corrupt humours or interest in base fawning, and the favour of present great men; therefore, if any resolute spirit happen to broach and maintain true principles of freedom, or do at any time arise to so much courage as to perform a noble act of justice in calling tyrants to account, presently he draws all the enmity and fury of the world about him. But in commonwealths it is and ought to be otherwise; for in the monuments of the Grecian and Roman freedom, we find those nations wont to heap all the honours they could invent—by public rewards, and consecrations of statues, and crowns of laurel—upon such worthy patriots; and as if on earth all were too little, they enrolled them in heaven among the Deities*.” So spoke one of our old English writers at a time when the Commonwealth of England had but lately before been little less disturbed than is the smaller community of medicine at this moment; and we are tempted to quote it now because we feel persuaded that the *spirit of centralization* is only the spirit of tyranny in another shape; and as we do not believe that any state did ever attain to true greatness or happiness under a tyranny, so do we not believe that our honourable profession of physic can ever flourish under the arbitrary domination of chance superiors.

We have been led to look at the proposed scheme of medical legislation in this point of view from having remarked the singular difference in tone and general style of observation conspicuous at the meetings of the profession held in London and the provinces. We said last week that our brethren in the

country seemed to us to see the thing rather as innocent rusticals than as sharp-sighted men of the world.

They appear so highly flattered that they have been thought worthy of his consideration by a Secretary of State for the Home Department, and that their calling, so little thought of by game preserving squires, cotton spinning manufacturers, *et hoc genus omne*, when they are *in health*, should have been thought deserving of attention in the Commons House in Parliament assembled, the House at the time consisting, be it remembered, of something under twenty members! that they have lost their head, and seem not to suspect the risk they are likely to be made to run, from what must be granted to be purely experimental legislation, calculated on no antecedent experience, irrespective of the actual state of the medical profession and the wants of the community, but based on certain peculiar views and opinions that may be sound and good, but which may also be worthless, and not more substantial nor better founded than a dream.

We will not pay our friends in the provinces the ill compliment of supposing that they are not perfectly sincere in their way of viewing the thing; what we complain of is that they do not view it aright; we will not insinuate that more than one of them had denied their presence at this or at that meeting of the profession where an opinion adverse to the Bill was likely to be expressed, because they had been limed with a twig of preferment artfully laid in their way, and to which, consciously or unconsciously, they had got fast.—No, the truth is, that we of London, who are free to think, and to speak as we think, see this legislative project in a totally different light from our brethren in the country. In fact, different classes of practitioners, both in town and country, see the matter dif-

* The Excellency of a Free State. 1656.

ferently, and judge it upon dissimilar and often totally opposite grounds.

In the metropolis we naturally look to the Colleges of Physicians and Surgeons as our heads; in the provinces, these institutions fade into comparative insignificance, and are little thought of. There has not been a meeting of the profession in the country, at which the supreme Council of Health and Education has not in itself, and without reference to its constitution, been most warmly approved of; in the metropolis, again, the Council of Health and Education is not generally relished, and we venture to say that three-fourths of the governing body, both at the College of Physicians and College of Surgeons, are decidedly opposed to it, and we, though belonging to neither of these bodies, heartily sympathize with them in their dislike of any and all such arbitrary domination. We would have our universities and our medical corporations free, not tyrannized over by any Secretary of State and his obsequious nominees. Uniformity may be a good; but it may also be an evil; the price paid for it may be more than it is worth. Our guilds and corporations are the legacy of our Saxon ancestors to us, their representatives, at the distance of a long lapse of ages, and let it never be forgotten that they have been the principal means by which the rights and liberties of the people have hitherto been preserved; they are that in fact which is most truly precious in our institutions; and they are precious because they habituate us to self-government. Let us not tamely give them up, then, nor revert to the constitution of society in the middle ages, when the burgher was nobody, but all were serfs at the disposal of the lord or petty sovereign of the district. If we have not achieved the degree of moral and mental eminence that would entitle us to a voice in the administration

of the affairs of these the corporations to which as medical men we either do or ought to belong, let us still struggle onwards in our efforts to attain it. All the world admit that we are improving, and our sons may achieve the distinction to which we have aspired in vain.

The cry that has been raised against corporations has been against the abuses of these excellent institutions; and how have the abuses crept into the administration of their affairs? because, commonalties have either had no share or only a very inadequate share, in the choice of the administrative body.

"Medical reform" as the watchword, appears, in fact, to us in London to signify one thing, and another thing in the provinces. In London, by medical reform we mainly mean the having a voice in the election of the administrative council of the college, or corporation, from which we have received our certificate of competency to practise medicine; this is what the London members of the Royal College of Surgeons especially have been contending for during so many years. But the provincial member of the Royal College of Surgeons cares not a rush about this, and by medical reform he often understands nothing more than a penal enactment against unqualified practitioners, of sufficient stringency and facility of application – fine and imprisonment on summary conviction before a magistrate, or some such trifle.

In London, what the General Practitioner insists on is, recognition by the body from which he has his diploma: he would raise himself higher than he is; he would have all the barriers that oppose his attainment of the highest places removed in the College of Physicians, but in the College of Surgeons especially; here it is a struggle for distinction; it is ambition, that "last infirmity of noble minds," that goads

him on. In the Country, the general practitioner thinks little of the College where he passed; he is beyond the sphere of its influence, and bends all his energies to achieving eminence by practice; he thinks less of his standing among his fellows; he is less ambitious in the same direction than the London man; instead of its being for name and fame, the struggle with him is rather for bread, or for its representative, money.

In London the medical profession stand on a totally different footing in society from their brethren in the country. In London we can be independent—vote for the tory or the whig, and even the radical candidate, at an election, as we incline: if we generally show deference and due respect to the clergy, which we do, we are yet never obsequious to them,—we are not afraid of the *cloth*, in short, and can always meet and speak of its wearer as he deserves; and then, if the high and mighty of the land show us the cold shoulder, which, by the by, they are occasionally very much disposed to do, why we can show them the cold shoulder in return. In the country it is all different; he who should vote for the whig candidate in one place, for the tory candidate in another, would be ruined in his worldly prospects. The country practitioner very commonly approaches the parson hat in hand; the body curer scarcely ventures to regard himself as on anything like a footing of equality with the soul curer; and as for the squire, or the great man, or great men of the district, they are truly a sort of *dii majores* to the village Æsculapius, not to be looked at without awe and reverence, and whose sovereign will and pleasure are to be received as the decrees of inevitable destiny.

In London we do not accept this Medical Bill more than we ever do any-

thing else, as the embodiment of absolute wisdom, nor with the same feeling of reverence as the Mussulman does the firman of his Pasha, which, perhaps, goes the length of making him shorter by the head; nor do we look at the thing merely in a selfish point of view, and as we are to be affected by it in our several capacities of physicians, surgeons, and general practitioners. Our country friends bow the head most dutifully in the first instance; but feeling the Right Honourable the Secretary of State's heel upon their precious necks, they by and by very respectfully suggest that certain amendments seem to them advisable; or they venture to say that they are not quite so handsomely treated as they thought they had reason to expect; or, waxing bolder as the sense of injury grows keener, they get the length of declaring that the Bill goes to the utter destruction of the class in the medical profession to which the great majority of its members belong. We have had no meeting in the metropolis at which the Bill has been spoken of by the chairman as a sort of inspired and perfect measure, whilst resolutions were passed, *nem. con.* utterly damnatory of every one of its provisions, save that of Registration, and even that found fault with because it was not compulsory!

Much of what Dr. Hastings said at the Derby Meeting of the Provincial Medical and Surgical Association, as well as the resolutions that were passed there, might satisfy us of the dim medium through which even our foremost men, our leaders in the country, see the Medical Bill. Dr. Hastings, for instance, said that the Provincial Medical and Surgical Association had asked Sir James Graham to bring in a Medical Bill, and he had done so shortly afterwards.

We are almost tempted to exclaim—

Sancta simplicitas! but that it would look disrespectful. The truth, nevertheless, is, that Sir James Graham only brought in the Medical Bill when he could keep it out no longer, and after the kibe on his heel had been repeatedly galled by the sharp toe of Mr. Macanlay, the representative of the interests of the University and College of Surgeons of Edinburgh,—a deputation from the former, and the President of the latter of which, had been in London some few weeks before, urging the thing on through their representative. Sir James Graham seems to have had an instinctive dread of the difficulty and opposition he was to encounter in legislating for the medical profession, and unquestionably hung fire as long as he possibly could.

When we travel beyond the English counties, and look to Scotland, we should say that the Edinburgh people, in their anxiety to put an extinguisher on the poor Apothecaries' Company—for which it is notorious they entertain the most sovereign contempt, mingled with a large measure of dislike—seem ready to make sacrifice of everything; of the independence of their ancient University, the *Academia Jacobi VI. Regis*, which has turned out so many doctors upon the world; of the College of Surgeons, which is an old and respectable institution, though its new building has got the dry rot in its timbers, and its funds are affected with a perfect diabetes, the outgoings far exceeding the incomings. The cry in the north is unquestionably for the *needful—rem, quocunque modo, rem!*

The Glasgow folks say little. The University there has never had great celebrity as a medical school, though it is an old and worthy place. In fact, Glasgow profits largely by the proposed measure of medical enactment. Its Faculty of Physicians and Surgeons will become a Royal College of Medi-

cine; and instead of getting nothing from the young men educated at the University there, it will rise into the licensing body, and put money in its coffers, by which it will of course become great and powerful,—money, which is the grand let or hindrance to a man's getting into the kingdom of heaven, being the one thing needful to securing consideration upon earth.

Aberdeen and St. Andrew's having given up trading in degrees, will be empowered to make bachelors, as they have heretofore made doctors, of medicine; and as a rose by any other name would smell as sweet—that is, as a bachelor's money will weigh as heavy as a doctor's, they are silent.

The Irish—the great body of the Irish medical profession, we mean—are like the Spaniards on the political map of Europe—nowhere. The Apothecaries' Company of Dublin are utterly mute, though their existence is threatened: have they, like good modern Romans, made shrift of their sins, and so prepared themselves to die? or do they sit, like worthy old Romans, in their curule chairs, composedly waiting the mandate of the Home Secretary that is to dispatch them? or,—and this is not so classical a simile,—do they admit themselves useless, and, like the cur in the same predicament, think it not worth while even to snap at the rope that is to hang them? They certainly comport themselves very differently from the Worshipful Society on this side the herring pond, who, with their "Statements," and "Addresses," and advertisements in all the daily papers, might not inaptly be likened to the pig on the morning of its demise, which very certainly lets all the neighbourhood know what is going forward.—But we must not be tempted into the light vein upon that which is really so serious; and so we close our lucubrations for the present.

MOVEMENT IN THE PROFESSION.

WE have little since our last. A meeting of the medical practitioners residing within the Hundred of Blackburn, was held on Wednesday last, and resolutions of the usual tenor were passed. The meeting felt the necessity of legislation for the medical profession; approved a Council of Health and Education, but not with the constitution of the one proposed; desired to record the strongest feeling of hostility to that part of the Bill which annulled all restrictions on unqualified practitioners; expressed the most clear and decided conviction that restrictive measures are indispensable alike in justice to the public and the profession, and that the Apothecaries' Company, by the course of study they had required, had done more to elevate the profession than any other corporate body.

A meeting of the medical practitioners of the town of Warrington was held at the Dispensary, on Tuesday evening, Nov. 22d, to take into consideration Sir James Graham's proposed Bill—Dr. Kendrick in the Chair; and after resolutions expressive of satisfaction with those provisions which were calculated to improve the character of the profession, to raise the standard of the education of its members, to establish a Central Council of Health, and the registering of all legally authorized medical practitioners,—they regretted that the Bill should allow mere pretenders to impose upon the public, and tamper with the health of the people, and expressed their opinion that a clause should be added for the purpose of effectually and speedily checking all illegal and unqualified practice.

Dr. Kendrick and Mr. Sharp were requested to confer with Mr. Blackburne, Member for the Borough, and Mr. Patten, Member for the County, on the objectionable clauses and deficiencies of the Bill, and a conversation ensued as to the best means of obtaining the objects sought for. It was finally resolved, that this meeting pledges itself collectively and individually to further the objects of the petition, by using their personal influence with the Members of Parliament in the neighbourhood, and through their friends who may have influence with those at a distance.

ADVERTISEMENT OF QUACK MEDICINES.

THE Editor of the Maidstone Gazette has fallen foul of us most unhand-somely, as we think, for merely illustrating one of the great difficulties in the way of legislating for the suppression of quackery, and the sale of quack medicines, from his own columns. We meant nothing offensive to the editor in doing so, nor did we insinuate that he was guilty of any moral delinquency in inserting such advertisements; it is customary to find them in all newspapers. He says we made too many of them; we always believed that duty was paid to government according to the diversity of items advertised, and reckoned them accordingly;—that the "Silent Friend" was one thing, the "Cordial Balm of Syriacum" a second, and the "Purifying Specific Pills" a third. But in this we may be mistaken; we are quite sure, nevertheless, that if 1s. 6d. covers the duty to government on these three items, the price of one ordinary advertisement does not pay for the half-column which their announcement occupies in the Maidstone Gazette. In so far as the revenue of the thing goes, we are sorry, for the editor's sake, that the three columns of quack advertisements, which we find in the very number of the paper in which we are so unhand-somely handled, is not four columns, as we think it must have been in the preceding number, from which we gave the particular heads. As for the other point upon which the editor attacks us, that is entirely between us and the individual referred to.

MISS MARTINEAU ON MESMERISM, AND MESMERISM AT THE SANATORIUM.

THE spirit of proselytism is a fine thing; the world would probably be a very dull place without it. The grand objection to it is, that it is commonly displayed on matters which are really of no moment in themselves; which are trifles both to society and individuals; in fact, though both society and individuals commonly enough look at them through so highly magnifying a medium that persuasion of their paramount importance becomes a canon of faith, a revelation both on outward and internal evidence. Miss Martineau had been long an invalid;

she was held, we believe, to have been labouring under organic disease of the uterus, yet happily the malady seemed slow in its progress, and if it confined her to her room, it appeared to abate little or nothing of her intellectual energy. We have at least one delightful work from the able pen of Harriet Martineau since she became a sufferer—we allude to “Life in the Sick-Room”—a book full of exalted philosophy, teeming with the truest spirit of piety and philanthropy. The disease of our gifted countrywoman, thank God! seemed slow to kill, and finally—and here we again say, thanks be to God!—it seemed to have come to a stand still.

“This is not the place in which to give any details of disease,” says Miss Martineau, (Atheneum, Nov. 23rd) “it will be sufficient to explain briefly, in order to render my story intelligible, that the internal disease under which I have suffered appears to have been coming on for many years; that after warnings of failing health, which I carelessly overlooked, I broke down while travelling abroad, in June 1839;—that I sank lower and lower for three years after my return, and remained nearly stationary for two more, preceding last June. During these five years, I never felt wholly at ease for one single hour. I seldom had severe pain; but never entire comfort. A besetting sickness, almost disabling me from taking food for two years, brought me very low; and, together with other evils, it confined me to a condition of almost entire stillness,—to a life passed between my bed and my sofa. It was not till after many attempts at gentle exercise that my friends agreed with me that the cost was too great for any advantage gained: and at length it was clear that even going down one flight of stairs was imprudent. From that time I lay still; and by means of this undisturbed quiet, and such an increase of opiates as kept down my most urgent discomforts, I passed the last two years with less suffering than the three preceding. There was, however, no favourable change in the disease. Everything was done for me that the best medical skill and science could suggest, and the most indefatigable humanity and family affection devise: but nothing could avail beyond mere alleviation. My dependence on opiates was des-

perate. My kind and vigilant medical friend,—the most sanguine man I know, and the most bent upon keeping his patients hopeful,—avowed to me last Christmas, and twice afterwards, that he found himself compelled to give up all hope of affecting the disease,—of doing more than keeping me up, in collateral respects, to the highest practical point. This was no surprise to me; for when any specific medicine is taken for above two years without affecting the disease, there is no more ground for hope in reason than in feeling. In June last, I suffered more than usual, and new measures of alleviation were resorted to. As to all the essential points of the disease, I was never lower than immediately before I made trial of Mesmerism.”

Few medical men of any experience will have the slightest difficulty in perfectly comprehending the state so graphically described by the sufferer. It is seen every day in women at the turn of life; and the grand mistake that is ever committed in regard to it is to look on mere functional derangement, accompanied by pain and excessive discharge, as organic disease—as cancer or polypus of the uterus. We are not fond of putting our brethren in the wrong in the *MEDICAL GAZETTE*; but if Miss Martineau's case were diagnosed as either cancer or polypus, and she recovered, even with the assistance of mesmerism, without a separation, naturally or artificially brought about, of the diseased parts, in either case, the first position we take up is that her medical advisers were mistaken in their view of the nature of her malady; that the disease was functional, not organic, and that the patient would have recovered—was in fact recovering, independently of mesmerism. There are curative means not suspected of the vulgar, of sovereign efficacy in such a complaint as that under which Miss Martineau laboured—*rest and time*. And we beg to assure her that *there is no “specific medicine”* for the malady with which she appears to have been mistakenly supposed to be affected, nor yet for that with which she was probably affected in fact—or if there be, it is a combination of the very remedies under the prolonged use of which she has most happily, as she says been “restored to the full enjoyment of active

days, and nights of rest, to the full use of her power of body and mind :” the remedies alluded to are *rest* and *time*.

Much of course will be made of Miss Martineau's case by the mesmerists—it is a successful one; it will be put into the mouth of rumour with the hundred tongues, and bruited over the length and breadth of the land. We do not observe that our friends the mesmerists are more candid than other enthusiasts and proselyte-makers; when they fail they say nothing of their failures; they are only loud when they succeed; like the lithotomists of old, who vaunted loudly enough their fortunate issues, but left the sod undisturbed that covered the dead men's ashes. The mesmerists tell us of the cases in which limbs have been amputated and breasts removed without the privy of the patient; they say nothing of the cases in which their *passes* and manœuvres had no influence in diminishing pain or locking up the senses in unconsciousness. A case of this kind, however, has just occurred at the Sanatorium, and we who are no mesmerists venture to make it known in its general features: Admission into the Middlesex Hospital was sought for a patient affected with a disease of the mamma, which, as being

deemed of an incurable nature, was believed to require extirpation. The patient, however, having friends among the mesmerists, they wished that she should enter the hospital on the understanding that they should be allowed to practice upon her, as well as the surgeon under whose immediate charge she was to be placed. This was objected to on the part of the surgeon, who, as officer of a public institution, did not feel himself warranted in countenancing any procedure in the efficacy of which he did not believe, and which was matter of dispute with the profession at large. He had no objections to the mesmerisers exercising their art on the patient; the breast ought to be removed; he was ready to remove it, the patient being in the mesmeric sleep; but he would not commit his public office to a measure the efficacy of which was generally discredited.

The patient was therefore removed to the Sanatorium; she was well mesmerised, and Mr. Arnott removed the breast. The operation was performed with rapidity and precision; yet not without the poor patient giving sufficiently obvious and distressing indications, both by movement and voice, of the pain she endured.

DR. GUY'S DEFENCE.

To the Editor of the Medical Gazette.

SIR,

I LOSE no time in appearing at the tribunal before which your reviewer has summoned

Taylor (p. 21.)

“Habit, it is well known, diminishes the effect of certain poisons:—thus it is that opium, when frequently taken by a person, loses its effect after a time, and requires to be administered in a much larger dose. Indeed, confirmed opium eaters have been enabled to take at once, a quantity of the drug which would have infallibly killed them, had they commenced with it in the first instance. Dr. Christison has remarked that this influence of habit is chiefly confined to poisons derived from the organic kingdom; and I quite agree with him, in thinking that the stories related of arsenic eaters, and corrosive sublimate eaters, are not to be credited. *There is no proof that any human being has ever accustomed himself, by habit, to take these substances in doses that would prove poisonous to the generality of adults. The only form in which I have known the*

me, and boldly plead “not guilty” to the charge.

Before I enter formally upon my defence, I must request the favour of your placing side by side the passages quoted in the review, supplying the omissions, which I have marked in italics.

Guy (p. 401.)

“*Habit.*—This has the effect of diminishing the influence of poisons derived from the vegetable kingdom, but of increasing that of mineral poisons. Thus, while opium, alcohol, and tobacco, lose their effect by repetition, and may be taken at length in doses which would poison a man not accustomed to their use, arsenic and the preparations of mercury produce more effect the longer they are taken. *To this general rule, however, there are marked exceptions; for, on the one hand, digitalis and strychnia, like arsenic and mercury, have a cumulative effect; and on the other hand, the less deadly mineral poisons, such as zinc and antimony, may be taken by healthy persons in continually increasing doses. It must be borne in mind, however, that even those substances to the action of which the system most readily adapts itself,*

question of habit to be raised in medical jurisprudence is this: whether while the more prominent effects of the poison are thereby diminished, the insidious or latent effects on the constitution are at the same time counteracted. The answer is of some importance in relation to the subject of life-insurance:—for the concealment of the practice of opium-eating by an insured party has already given rise to an action, in which medical evidence on this subject was rendered necessary. As a general principle we must admit, that habit cannot altogether counteract these insidious effects of poisons; but that the practice of taking them, is liable to give rise to disease, or impair the constitution."

I would submit these passages to the candid judgment of your readers, and ask whether they can detect anything approaching to plagiarism in that extracted from my work. Both passages treat of familiar facts, both of them use familiar illustrations; but here the resemblance ceases. The entire passage is not only widely different from that quoted from Mr. Taylor's Manual, but though brief, may fairly claim to be more full, more definite, and as far as originality is possible in such a matter, more original.

Christison (p. 28.)

"On the contrary, the tendency of *habit* when it does affect their energy, is, with a few exceptions, to lessen it. By the force of habit a person may take without immediate harm, such enormous quantities of some poisons as would infallibly kill an unpractised person, or himself when he began. There have been opium-eaters in this country, who took for days together, ten ounces of laudanum daily."

In contrasting these two paragraphs, I am far from wishing to bring against Mr. Taylor the odious accusation which has, in my own case, been built upon so slender a foundation. I merely contend, that there is a much closer resemblance, both of matter and words, between these two passages, than between those of which you have made, as I think, so mistaken a use. If I am to be condemned on such grounds, Mr. Taylor cannot escape your censure; but the imputation would be as unjust in the one case as in the other.

Before I leave this part of my defence, I cannot but express my regret that the passage of which a part only was extracted from my work, had not been quoted in full. The parts that have been omitted are precisely those which give a character of individuality to the entire extract. In reference to this part of the charge, I have only to add my unqualified denial of the justice of the imputation it is intended to convey.

produce permanently injurious effects on the system. Thus, alcohol causes disease of the lungs, liver, kidneys, and brain; tobacco, however frequently repeated, still excites the circulation, and opium raises the spirits, and gives increased activity to the mind."

If such very distant resemblance as exists between the opening of these two paragraphs is to be taken as proof of plagiarism, no author who has ever written can hope to escape from such a charge. I would illustrate this position by placing side by side a part of the above passage from Mr. Taylor's Manual, and a short paragraph from the standard work of Dr. Christison.

Taylor (p. 21.)

"Habit, it is well known, diminishes the effect of certain poisons:—thus it is that opium, when frequently taken by a person, loses its effect after a time, and requires to be administered in a much larger dose. Indeed, confirmed opium eaters have been enabled to take at once a quantity of the drug which would have infallibly killed them had they commenced with it in the first instance."

I shall now examine seriatim the principal accusations brought against me by the reviewer, and I shall use my best endeavours not to misunderstand or misstate them. It appears that my accuser had no sooner dipped into my work, than he "became strongly possessed with the idea, that he had already read the book; the very turn of the language and phrases employed, struck familiarly on his eye," "every illustration seemed as familiar to him as the face of an old friend," and he exclaimed, "we have read all this before." He then proceeds to confirm his impressions by placing the two books before him, and conning them "paragraph by paragraph, page by page," and arrives by this laborious process at the conclusion, "an apple cleft in two, is not more twin: one face, one voice, one habit, and two persons—a natural perspective, that is and is not!"

I cannot hope, by a simple assertion, to rebut this very grave accusation. I must,

therefore, at the risk of occupying more space in your valuable pages than you can well afford me, and of wearying your readers, beg permission to contrast two passages treating of the same subject, that your readers may judge for themselves, by a single example, of this asserted resemblance of

Taylor (pp. 19 and 20.)

"Thus then, I think, we may draw these conclusions:—1. That the remote influence of poisons is sometimes conveyed through the medium of the blood. 2. That it may be conveyed by contact with the sentient extremities of nerves, probably of the ganglionic system. 3. That some poisons may act in both ways at different times." "Those who advocate the theory of absorption, in opposition to that of sympathy, suppose that they thereby account for the cause of death; but nothing can be more unfounded. Admitting that every poison entered into the blood, it would yet remain to be explained how it operated when there, to destroy life. Whether the poison be in the midst of the blood in an external wound, or circulating in an artery or vein, it kills, and the last mentioned theory has at least the advantage of affording an analogical explanation of the mode in which the fatal impression is conveyed, in the two cases."

These are solitary passages, but I am willing that the entire chapters from which they are taken should be compared, and I confidently assert that in style, arrangement, mode of illustration, and general views, there is as marked a difference as it is possible to meet with in any two authors writing on the same subject, and consulting the same authorities. The arrangement of the chapter is as nearly as possible that sanctioned by the high authority of Dr. Christison, from which I saw no good reason materially to depart.

I am far from laying great stress on a comparison of isolated passages, and I should not attach much importance to a score of them; but a single comparison may serve to show the injustice of the sweeping censure of the reviewer. It is something to prove my independence even in a single instance; and I am sure that any one who will take the pains to contrast Mr. Taylor's view of the *modus operandi* of poisons with my own, will admit that there is as much difference in the style, arrangement, and conclusions, as the most captious critic could desire.

Following my reviewer step by step, I must now correct an error, which, though unimportant in itself, is thrown into the scale against me. "We remember," he says, "Mr. Taylor deeply versed in medico legal lore, when Dr. Guy could have been little more than a school-boy—nothing

style and matter. They both refer to the *modus operandi* of poisons, and I select them because the extract from my own work is taken from the very chapter which contains the passage already cited, and is separated from it only by two pages.

Guy (p. 399.)

"The theory, then, of the absorption of poisons, and their application by means of the blood to the organ on which they produce their fatal effect, is one firmly established by experiment, and, probably, admitting of universal application. In order to prove the possibility of an immediate effect upon the nerves, independent of absorption, it would be necessary to guard against the access of the poison to the lungs; and if, after this precaution, the effects should be found to manifest themselves in less than three or four seconds, the possibility might be admitted. Till such an experiment has been performed, the theory of absorption must be held to explain the fatal effects of poisons, and the theory of the action of poisons by sympathy, or in other words, through an influence directly communicated by the nerves, must be rejected."

more than a medical student, certainly;" and he then proceeds to insinuate that having attended Mr. Taylor's lectures at Guy's Hospital, taken copious notes, and put into successful practice my own suggestions for the keeping of a common-place book, (which, by the by, are most strangely and perversely misrepresented,) I have concocted my Third Part out of the said notes, and extracts from the Manual, with some few interpolations from Dr. Christison's work on Poisons.

Now the real facts of the case are these. Some seventeen years since, Mr. Taylor and myself were fellow-pupils at Guy's Hospital, in attendance upon the same course of lectures. He was my senior both in years and standing as a pupil, but as he was not then a lecturer on Medical Jurisprudence, I did not at that time enjoy the advantage of his instructions. My obligations to Mr. Taylor are of a much more recent date. Some of your readers are aware that in the summer session, immediately succeeding the lamented death of my predecessor, Dr. Fergus, Mr. Taylor delivered a course of lectures at King's College. These lectures I attended, but without taking notes. I had, moreover, through Mr. Taylor's kindness, the additional advantage of attending a course of his familiar demonstrations in Toxicology, at Guy's Hospital, and of these I did take some very short, but useful notes, referring almost

exclusively to the tests for poisons. To say that I have not profited by these opportunities would be to convict myself of inattention, but the advantage I derived from them was not of the kind supposed in the review. They were of some slight assistance in the preparation of my lectures, but they form no part of my work. For any merit which either may possess, I am chiefly indebted to the admirable treatise of Dr. Christison, to which I have acknowledged my obligations in the preface, and by very numerous quotations and references in the body of the work. These, I presume, are the few interpolations to which the reviewer refers.

If, then, in preparing the third part of my work for the press, I have laid myself under obligations to Mr. Taylor, it is by the use I have made of his Manual. Now, I not only do not intend to deny having made use of Mr. Taylor's Manual of Medical Jurisprudence, but I make no secret of having, as I was bound to do, used it extensively. And I have done so in the very face of a threat which might have well deterred a timid person from touching it. I knew that what I was about to publish would have to undergo the ordeal to which it has been submitted, that it would be minutely scrutinized with a view to discover parallel passages, and so-called plagiarisms, and that I could only escape censure by foregoing the benefit of Mr. Taylor's labours. I had no difficulty in making up my mind to the course I should adopt. Mr. Taylor's work abounds in valuable facts which have come under his own notice, or have been communicated to him by others, and in cases extracted from the Foreign Journals. The tests for poisons are also given at considerable length, and with much minuteness, and the entire subject of Toxicology is treated in such a manner as to make a frequent reference to it incumbent upon every succeeding writer on the same subject. Such being the character of Mr. Taylor's work, I should have been chargeable with neglect if I had not made use of it. Accordingly I have quoted several cases, with due acknowledgment, and that I might display my obligation to the full, have given him the credit of bringing together several cases to which without much loss of time I might have referred. As such a course might have laid me under the imputation of making an undue use of another's labours, I have preferred in this, as in many other instances, to quote the author who first made such cases our own. This, then, is one use I have made of Mr. Taylor's work; and in this, at least, I am not guilty of omitting the due acknowledgment. I have also referred to Mr. Taylor's work in the expectation of finding additions to our tests for poisons, which it would be necessary to notice; but as, in my opinion,

he has not been fortunate in this respect, I have been under no temptation to appropriate his discoveries. I certainly was not aware that the effect of the application of heat to the arsenite of copper was claimed by or for Mr. Taylor, as a discovery which required acknowledgment at my hands. That property of the arsenite of copper, as well as the sublimation of the metal on applying heat to the mixture of that substance with charcoal, is stated in p. 264 of Dr. Christison's work. I was, therefore, under no necessity of resorting to the Manual. The oversight which I have committed proves of how little importance I deemed the test, for a moment's consideration would have sufficed to show that a ring of metal could not be procured from a combination of arsenious acid with a base; and that this is a mere oversight is proved by a reference to page 465, in which I state that arsenite of copper, when heated with charcoal, yields a metallic sublimate.

In the paragraph which immediately follows the claim of originality set up for Mr. Taylor relative to the effect of heat on the arsenite of copper, the reviewer, with a view of strengthening his position, finds fault with me for not correcting a deficiency in Mr. Taylor's Manual which does not exist. I presume that it was not Mr. Taylor's intention to save his readers the trouble of calculating for themselves the quantity of any one of the salts of lead that must have existed in a fluid from which a certain number of grains of sulphuret of lead have been procured. The calculation is not of surpassing difficulty, the necessary data are to be found in any chemical book, and I should not despair of being able to work any problem of the sort, with which the reviewer may please to favour me. I have not yet quite forgotten the simple rule of three, nor am I altogether ignorant of the fact, that "the question in a case of poisoning is never as to the quantity of metallic lead in a salt, but as to the quantity of the poisonous salt that has been administered." Such stupidity is scarcely to be expected in one who has the gift of imitating with success the style of other writers, and of "disguising the parentage of his matter, arrangement, and conclusions."

I shall take this last sentence, with one slight addition, as embodying the substance of the charge brought against me. I am arraigned for using the words, and borrowing the matter, arrangement, and conclusions of my work, from Mr. Taylor, without acknowledgment. I have already pleaded not guilty to the first two counts of the indictment, and I now assert my innocence as to the last two. The arrangement of the entire Part coincides very closely with that adopted by Dr. Christison, and has been little influenced by my perusal of Mr. Taylor's work,

or my recollection of his lectures. That of the several chapters is exactly such as I have adopted in the first two parts of my work, which were published before Mr. Taylor's Manual, and the order in which the several tests are placed is one peculiar to myself, and which I have always followed in my lectures. The conclusions at which I have arrived are also widely different from, and sometimes diametrically opposite to, those of Mr. Taylor. If it had been possible to treat the facts of chemistry as subjects of dispute, or to display originality in chemical equivalents, I should have had a better chance of escaping the censures of the reviewer; but unfortunately the difference between one author and another in treating such matters must be necessarily very slight.

To conclude, I have no wish to underrate my obligations to Mr. Taylor, or his Manual; but I do most emphatically deny that I have made an undue use of the knowledge which I have derived from either. In the third, as in the two former parts, I have done ample justice to his labours, and have not intentionally omitted the acknowledgment of my obligations to him. I repel with indignation the unjust charge of my reviewer, and accuse him of treating me with gross injustice. He has, according to his own statement, read the third part of my work paragraph by paragraph, and page by page, and yet he has the shameless effrontery to state that it is nothing more nor less than a condensation or abridgment of the corresponding part of Mr. Taylor's work. He has examined the two books minutely, but has wilfully failed to discover in them any difference of arrangement, or any opposition of sentiment. Down to the very style all is one piece of unmitigated plagiarism. He has not thought fit to notice the wide difference between the views of Mr. Taylor and myself, as to the *modus operandi* of poisons, nor the laborious analyses of cases "taken at the source, and not at second-hand," and establishing general results of which I have already had one opportunity of testing the importance. The chapter on arsenic, containing the most extensive analysis of cases on record; a new, and, as I think, not unimportant suggestion for distinguishing the crusts of arsenic and antimony; a description of their differences founded upon repeated experiment, and calculated to modify the statements of Mr. Taylor concerning them; and a strongly expressed doubt of the value of one of the few new tests proposed by him; is not even mentioned. The peculiar and distinct arrangement of the tests for poisons, and indeed every indication of labour, thought, and originality to be found in the book, is passed over in studied silence, lest it should weaken the force of this most unjust and odious accusation.

There may be a difference of opinion as to the extent to which one author is allowed to make use of the work of another; but there can be but one opinion as to the conduct of a reviewer who thus wilfully omits every qualification of a charge which a sense of justice and common humanity alike require to be stated with all its limitations. In my own name, and on behalf of every living author, I protest against the course which your reviewer has chosen to adopt. If it is allowable to assert without a shadow of proof that even the very style of an author is but the transcript of some contemporary work, what shall prevent this charge from being flung back with fearful effect at the reviewer himself? It is not the least inconvenience of anonymous writing, that while it exposes an innocent man to the safe attacks of an enemy or a rival, it creates suspicion as to the person of the writer himself, which, if the review is more than usually severe and one-sided, never fails to attach to the party who may be supposed to have the greatest interest in the attack. In committing one injustice, you open the door for a thousand.

I have now obeyed your summons, and if what I have written is of inconvenient length, I would remind you of the wide difference that there is, and must be, between an accusation and a defence. I request the insertion of this letter as an act of justice, and I trust that you will not deem the terms of my reply stronger than the occasion warrants. If you should be inclined to think them uncourteous, I beg you to peruse once more the review which has called them forth.

I have the honour to be, sir,

Your obedient servant,

WILLIAM A. GUY.

15, Bloomsbury Square,
Nov. 18th, 1844.

[We are very far from having any desire to put Dr. Guy irrevocably in the wrong; on the contrary, we would fain see him place himself in the right. Did his explanation prove satisfactory to Mr. Taylor and to the profession, we should not be behind-hand in withdrawing the charge of literary plagiarism made in our pages, and of making Dr. Guy the *amende* in behalf of our reviewer.—ED. GAZ.]

VACCINE LYMPH.

To the Editor of the Medical Gazette.

SIR,

I HAVE during the last summer experienced much difficulty in obtaining active vaccine virus; through the kindness of a friend I have at length obtained some, with which I am now vaccinating the paupers of a large parish. The effects have proved very satisfactory; the vesicle is well defined; the

subsequent areola extensive; the axillary glands are for a time painful, and the general constitutional symptoms well marked. My object in addressing you is to state, that having now, and hoping to have for some time to come, a tolerably good supply of this lymph, I shall be most happy to furnish with a portion of it any of your readers who may choose to apply for it. A similar notice inserted in the Provincial Medical and Surgical Journal a few weeks since, produced me sixty applications. Experience induces me to suggest to those gentlemen who may avail themselves of this offer, that it would save me much trouble, and some little expense, were a pre-paid envelope, ready directed, to be enclosed to me.

It is very desirable that the inefficiency of the virus supplied of late by the National Vaccine Establishment, Rupert Place, Fitzroy Square, should be taken up, and commented upon in the way which its importance deserves: it was a subject of complaint with three out of four of the late applicants for lymph; and my experience quite coincides with theirs.

Yours obediently,
THOS. P. FERNIE.

Kimbolton., Hants,
Nov. 23rd, 1844.

[We also observe by *Casper's Wochenschrift*, of Oct. 5th, that Dr. Bremer, Director of the Vaccine Institution of Berlin, has a supply of *original lymph* from the cow, with which he is ready to furnish applicants from home and abroad through post-paid letters addressed to him.—ED. GAZETTE.]

LACERATION OF THE RECTUS FEMORIS MUSCLE.

I WAS called to a baker, about 50 years of age, who had slipped in coming down a stair with a measure of corn in his hands, the edge of which, in the effort he made to save himself from falling, he had pressed rather than struck violently against his thigh some short distance above his knee. He only reached his home with the greatest difficulty, dragging the injured limb behind him. On examining it, the integument and bone were found uninjured, but there was a distinct gap or depression, 1 inch in breadth, and by $\frac{1}{2}$ inch in length, in the thigh, over the knee: the rectus femoris was obviously torn through in this situation, and its belly lay contracted upon the anterior aspect of the thigh. The pain was trifling even when the limb was flexed and extended, but the patient could neither extend his limb himself nor stand upon it. The limb was put into a position calculated to relax the muscles in front of the thigh in the greatest degree, and the belly of the muscle was pressed down by

means of bandaging as much as possible. Not a trace of inflammatory reaction supervened, and the patient was soon in a condition to get about again with the help of a stick; by and by he recovered completely.”
—*Dr. C. Kohler, Medicinische Zeitung*, No. 22, 1844.

MELANCHOLIA PUERPERALIS ATTONITA.

A FEMALE in her first confinement had the misfortune to *overlie* her four days old infant, and in addition to her own distress, was scolded unmercifully by her husband, a violent man. The change that came over the poor woman was so great and sudden, that on my entrance into the room I saw death in her features. Her consciousness was intact, she had no fever; the vegetative functions appeared all to be unaffected; but the expression of the countenance was sorrowful, suffering, and yet indifferent—indescribable, but which once seen can never be forgotten. My unfavourable prognosis was not believed: the patient was comfortable, and they sent for another physician, who prescribed antiphlogistic means, apprehensive of puerperal fever, and then, when the powers of life began suddenly to fail, cordial and stimulating remedies; but all in vain; in three days the patient was a corpse.

This was no case of puerperal mania, nor yet of puerperal typhus; the cause of the mischief, as I apprehend it, lay in a kind of paralysis of the sensorium commune; not material, but mental, and striking at the very roots of life. I saw that we were without means of dealing with so serious a mental impression as had here been made. Although there is little in a name, yet I have ventured to propose one for this form of mental disease; or if the reader prefers it he may say that the patient died of a broken heart.—*Dr. Lion, in Casper's Wochenschrift*, No. 33.

OVARIAN DROPSY, DISCHARGING ITSELF BY THE UMBILICUS.

A WOMAN, 23 years of age, had suffered for two years with dropsy of the right ovary. When the swelling had increased to a great size, the parts around the navel began to get hard; the navel itself projected, and finally gave way, upon which, and for a long time afterwards, there followed a discharge of purulent lymph, accompanied with a notable and progressive diminution of the abdominal enlargement. Shortly after her recovery this woman married, became pregnant, and gave birth to a strong boy. After delivery the abdomen did not shrink in the usual degree; by and by, on the contrary, it increased in size again, which increase was found owing to an ovarian dropsy, which

went on augmenting in size, and at length terminated in the formation of an abscess as on the former occasion.—*DR. LAMBRECHT, Medicinische Zeitung, No. 30, 1844.*

AMNESIA COMPLICATING ACUTE RHEUMATISM.

A GENTLEMAN, by exposure to cold, contracted a fixed rheumatic pain in the neck, for which he only sought assistance eight days after the commencement of the attack. He had already been subject to rheumatism, but had always recovered without medical assistance till now. He was ordered dry cupping over the part affected, and fifteen drops of colchicum wine every two hours. He was also desired to keep himself warm; but having, instead of this, exposed himself anew to cold, I was required to visit him several times on the next succeeding days, on account of several new and rather alarming symptoms, which led me to infer a metastasis of the rheumatism to the membranes of the brain. The patient could only utter, with extreme slowness, and stammering all the while, a few unconnected words, and had no power to name the articles of every-day life that were set before him, such as a book, a knife, a pen, &c.; the patient, nevertheless, could write their names down, and appeared perfectly to understand all the questions that were put to him concerning them. When the name of any thing placed before him was given him, he could also repeat it readily enough. The motions of the tongue appeared to be unaffected. The application of eight cups, with scarification behind the ears, succeeded by a blister, completely removed this condition. The rheumatism reappeared in the neck, and required further treatment.—*DR. LINSEM, in Medicinische Zeitung, No. 20, 1844.*

LECTURES
ON THE
NATURE AND TREATMENT OF
DEFORMITIES,

*Delivered at the Bloomsbury Square
Institution.*

BY R. W. TAMPLIN, F.R.C.S.E.
Surgeon to the Institution.

*Deformities of the knee-joint—Genu valgum
or knock-knee—Genu valgum with out-
ward inclination of the opposite knee—
Genu valgum with curvature of the bones.*

TO-DAY, gentlemen, we shall proceed to the consideration of the deformities, or malpositions, to which the knee-joint is liable; the first or most simple form of which is that known by the name of genu valgum, or knock-knee. This deformity is met with at all ages, from infancy to maturity, but rarely, if ever, in the prime or in the decline of life—at least not singly. It consists in a relaxation and elongation of the internal lateral ligament, and the crucial ligament must also yield more or less; for in the healthy or normal condition of the joint these ligaments admit of the smallest possible amount of lateral motion. This appears to be the primary condition; and if you will direct your attention to the position of the joint, and observe that it is at a distance from the point or points of pressure in walking or standing, you will easily perceive that if the superincumbent weight of the body is thrown in any but a perfectly straight direction, with regard to the axis of the joint, if the tibia on which the femur rests is in an oblique lateral direction instead of a perfectly horizontal one, corresponding with the articular surfaces of the condyles of the femur, that this bone must press, in walking or standing, in an indirect and abnormal position, producing thus mechanically an increase of the deformity, of whatever kind it may chance to be; and when the foot is felt to incline outwardly, and the

knees commence to touch each other, the malposition, as a rule, becomes daily increased in proportion to the extent at which the feet are separated from each other; the greater the distance, according to a principle in mathematics, the more powerful will be the effects of pressure occasioned by the weight of the body, and the more rapid the increase of the deformity. The deformity is non-congenital—at least I have never seen a congenital case, nor can I imagine how it could occur, provided we admit that congenital distortions arise from malposition in utero. The general cause is debility, and the specific causes the effects of dentition, the various eruptive diseases to which all children are liable, also whooping-cough (in children). In youth, the cause generally assigned is carrying heavy weights, or standing for hours in one position; but although these are perhaps the immediate causes, general debility is the primary or remote one: for in whatever circumstances of life we meet with it—and it occurs in all, but more especially in the lower class—an unhealthy constitution generally exists, or has done, during its early stage. It is by far the most common deformity met with, excepting rachitic curvature of the bones, with which it is frequently combined, and occurs, as I have said, at all ages up to the adult stage. It exists alone, but very frequently, nay, it almost invariably, will be found combined with the tibia and fibula, and occasionally the femur also, thus showing the general state of the patient's constitution: occasionally it is single, or confined to one of the knee-joints; more frequently it is double, in which both are affected, and generally one more severely than the other. At other times, it is combined with outward inclination of the other knee-joint, thus giving the patient a most curious appearance in walking of one joint running after the other, the two joints forming an angle more or less acute. It is very frequently combined with spurious valgus, which owes its origin to the oblique

position of the articular cavity of the ankle-joint, occasioning a constant stretching and consequent yielding of the deltoid, or internal lateral ligament—the pressure being exercised on the inner portion of the transverse

arch of the foot: the ligaments connecting the arch (and which I mentioned to you when speaking of talipes valgus), also stretch, and allow it to sink, and then to form a flat foot, (Fig. 1.) In the early stage, then, you

FIG. 1.

An illustration of knock-knees taken from a child aged 6 years, in which the eversion and flattening of the feet was most severe, as may be observed.

have this yielding or debility of the ligaments of the knee unattended with any additional obstacle; as the deformity continues, you will find the biceps, flexor femoris, from being constantly somewhat shortened, offer more or less resistance, which resistance becomes proportionably increased according to the length of time it has existed, on the one hand; the state of health of the patient on the other; so that even in children you will find this muscle, together with the fascia lata, to which the vastus externus is attached, exceedingly rigid and tense upon any attempt to place the leg forcibly in a straight line; the whole of the deformity existing independently of, and unaccompanied with, any disease in the articulation, ligaments, or muscles attached; unless, indeed, debility be considered as a disease. You frequently have, also, the large tumid abdomen, indicating an unhealthy state of the secretion, and symptoms of mesenteric disease. When the deformity exists to any extent, the internal condyle of the femur pressing much inwardly, the leg presents an unsightly appearance, because the gastrocnemius does not follow the position altogether, but recedes from the tibia and femur on the internal side, and passes in a more direct line to its origin, thus giving the internal condyle of the femur an appearance of increased size, and more full development than is natural: this effect is not, I believe,

actually produced. I have been consulted, from this very circumstance, by parents whose children had this deformity. They imagined that an actual enlargement had taken place, whereas the appearance arose from the cause mentioned, and from the children having grown rapidly with a diminished development of the muscular system generally. There is also an enlargement of the tubercle of the tibia frequently met with, and occasionally to a great extent, giving it the appearance of an exostosis, and forming quite a sharp point at its extremity, as if protruding from the skin, and almost leading to the supposition that a separation of the epiphysis had taken place, which I cannot imagine actually to occur; nor can I divine the cause; I only know that it is so, and that this also adds to the deformed appearance, and frequently occasions more anxiety to the parent than the deformity itself. It is not, however, of any moment, only requiring to be protected from pressure during the treatment; for I need not tell you that a spicula of bone would, with a very small amount of pressure, occasion a wound in the skin. The tibia and fibula will be found conjointly curved, with this affection, outwards, forwards, or inwards; very frequently the last. The tibia appears perfectly straight in its two upper thirds, and then diverges outwardly, so that when the knees are brought into their proper position

the feet will remain two inches, or more, apart. A child thus affected, excepting only on the first onset, presents a very awkward appearance, and walks in a most irregular and unsteady manner of necessity, as from the weakness and relaxed condition of the ligaments of the knee and ankle-joints he possesses no steady support or fulcrum on which the moving power can act; and instead of the leg being planted firmly on the ground the moment that it is brought forward, and placed in the position in which the extensors and flexors could act upon it, during the effort made to progress, and when the weight of the body is thrown upon it, the joint, or joints, yield more or less, according to the severity of the deformity, and thus occasion the irregular and unsteady motion of which I spoke; for at no time are the joints kept in their proper position, or restrained with their natural, healthy firmness; added to which, when the deformity is severe, one knee overlaps the other, and encloses it at each step taken—the only method the patient possesses of walking, the feet being too far apart to allow of the knees being brought into a parallel position: the consequence is that the child will be constantly falling down, or tumbling about, and that he suffers additionally in health from the inability to take proper exercise without experiencing pain and great inconvenience. You must be well aware that it requires but little irritation or annoyance, constantly kept up, to interfere with the health of a child. This irregularity of movement keeps up an undue, and oftentimes very considerable motion in the spinal column; and when the affection is confined to one extremity you will occasionally find, as I mentioned to you when speaking of the deformities of the feet, a tendency to lateral curvature, and very frequently the foundation is laid of spinal deformity; as when the ligaments of the spine are thus kept constantly in motion, I mean an increased motion, producing elongation, the spine will yield in any position, which, from whatever cause, may be longer maintained than any other; for it cannot be expected that they can, when thus kept constantly in motion, acquire that degree of solidity and consolidation necessary to hold the spine and muscles in the erect position. Occasionally I have found talipes equino valgus to exist, arising from paralysis of the anterior tibial muscle, from irritation, or disease of the brain or spinal column, resulting, in addition to the previous deformity: this is, of course, a much more serious condition than either of those before mentioned, oftentimes involving the necessity of the patient wearing support for life.

I mentioned to you that it is combined with outward inclination of the opposite

knee; a case of which, in the adult, is now in the charity, and of whom this is the cast. (Figs. 2 & 3.) This also occasions, at times, increased motion in the spinal column. As the body cannot be kept in an erect position, except at the cost of the spinal column—for you observe that in consequence of the angle of the knees conjointly, the pelvis will be, at times, in an oblique position, and if the spinal column maintained itself perpendicularly the whole of the upper portion of the body would be on one side, or hanging over, a position which would render it difficult for the patient to take exercise, or continued exercise; whereas, by the yielding of the spine, an erect position is maintained, although the body presents a series of angles more or less acute, and of course increased deformity. This outward inclination of the knee-joint rarely occurs in this affection, except in combination with curvature of the tibia itself, as may be easily seen if you cover the upper part of the thigh and leave only the leg below the knee uncovered, when the tibia will be found to have deviated more or less from its straight condition. The foot will be, however, with this, somewhat displaced, generally everted, from the articular cavity of the ankle being out of its proper position, the astragalus lying obliquely in the cavity. In this case the whole foot becomes altered in position without any change in the relative position of the bones or ligaments themselves, the astragalus alone being displaced. This applies more especially to young children; as in strong boys, or young men, you will find just the reverse, from the power exercised by the muscles to prevent this alteration in the position of the astragalus.

The foregoing observations apply principally to young children. This deformity arises, then, at any period during the growth of the individual, and after infancy will be found to occur between the ages of ten and eighteen. It comes on gradually and imperceptibly, without any illness or apparent loss of strength; and the first thing that attracts the patient's attention to it is the knees knocking or rubbing the one against the other: as it proceeds, a weakness is experienced in the joint, more especially on the inner side, which seems to be occasioned by the stretching of the internal lateral and crucial ligaments. The feet are then noticed to diverge from each other, and very frequently to turn in, presenting the appearance of slight talipes varus. (Fig. 4.) This position, however, is only present when the patient is walking or standing, and ceases when the legs are not exercised. You will find, upon examination, that there is, however, a greater amount of lateral motion in the ankle-joint than is natural, and that the internal lateral or deltoid ligament is somewhat stretched. You will rarely find talipes valgus between

FIG. 2.

FIG. 3.

FIG. 2. An illustration of knock-knee of one leg, and outward inclination of the other, taken from a patient aged 18.—FIG. 3. The same after treatment. It must be observed, however, that the outward inclination is only removed during the time the instrument is on, an interspace existing between the internal condyle and head of the tibia, shewing that the deformity in that leg is owing to a curvature in the bones, altering the relative position of the articular surfaces.

the ages of 10 and 18, as a consequence of the deformity, owing, I imagine, to the general health being stronger than in the young subject, and to the greater power and tone of the muscles generally, which, by their action, are enabled to protect the ligaments from so great an amount of pressure, and consequent stretching; whereas in children thus affected very little assistance can be expected from this source, inasmuch as general debility to a much greater extent is constantly present, allowing of the attachments of the bones and joints to yield from the slightest causes.

You will never meet with curvature of the bones combined, unless that curvature has arisen during the earlier period of life, the bones presenting and possessing their natural and normal length, size, and form, but you

will be struck in these cases, more particularly, with the apparent enlargement of the internal condyle of the femur which I mentioned to you, and which is more striking in youth than in childhood, from the general outline being as a matter of course more clearly defined, and also from the gastrocnemius, from the change in the relative position in the bones, leaving as it were, the internal condyle and going direct to its origin: the question then, arises, what is the change that takes place, causing the bones thus to alter their position? The objects who present themselves are generally those whose occupations require them to be for many hours in a standing position, as a compositor for instance, or those who are obliged to carry heavy weights and to undergo much bodily fatigue, combined, perhaps,

FIG. 4.

with an insufficient diet—as bakers' or butchers' boys. In these cases, then, it would appear to occur, first, from over exertion; 2dly, from general debility occasioned by that circumstance, and by bad or insufficient diet; in this way the passive agents of attachments of the joints have more to do, and a greater force is exercised constantly upon them, than natural, from the muscles becoming fatigued and unable to continue that uninterrupted action which at all times takes place in perfect health, with an amount of power constantly equal to their labour, but the moment the muscles become over fatigued, the ligaments are then called upon to assist the muscles in supporting the body in the erect position, and from their inability to do this constantly, without yielding and becoming elongated, the knee-joint yields inwardly in proportion to the unusual stretching the ligaments are subjected to, and when once the force is directed obliquely, instead of directly on the articulating surface, the yielding proceeds more or less rapidly with the deformity. When the deformity is considerable (as in this cast), and has been so for

some years, does the articulating surface itself alter in position, or does the internal articular surface of the tibia diminish in size, and allow the internal condyle of the femur to sink? Or does the internal condyle itself alter in, and increase in size and project more than it does in its natural form and size? I do not believe that either of these changes takes place, although in the case mentioned a separation might be felt between the tibia and femur internally, after the legs were brought into a straight line. My opinion is, the articulating extremities are not in fault, certainly not primarily, and the only doubt that exists in my mind is the possibility of the articular surfaces growing in this position, supposing the deformity to have arisen during the early period of childhood. We have had patients at this charity, the most severe cases met with, in whom, after many months' treatment, when the legs have been straightened, and where there was no curvature of the bones, the joints have maintained their position, without support of any kind, and without the joint yielding in the slightest degree—even the case of

which this is cast ; the patient being eighteen years of age, within twelve months he could stand and walk without any artificial support, and without the joint maintaining this position. I have a patient, aged seventeen, at this moment, who was operated upon eighteen months since, and whose joints now are perfectly recovered, and he can maintain their proper position unassisted. In children I have not seen an exception to this. But the case mentioned to you before certainly is an exception to this, as at present it is three years since the operation, and he cannot walk without his supports, so that although I believe no alteration takes place, certainly none by attrition—for I cannot conceive the possibility of the cartilage being reproduced after it has been rubbed down—yet it is a question on which, from our present experience, I am unable to speak positively. I can understand the articular surfaces of the tibia and femur being altered in position from curvature in the shafts of those bones, but this is not a change in the articular surfaces themselves, but in the support or pillars on which they rest : look, for example, at the bones of a congenital talipes varus, a skeleton of which I have seen ; we do not find the bones suffer by friction, or the articular surfaces altered, except in the slightest degree, although the malposition is extreme, and in a joint upon which the whole weight of the body is supported, so that this idea does not appear to me to be founded on fact. But, if the bones are curved, and thus alter the position of their extremities, then I can understand how the articular surfaces become perfectly adapted, and in fact produce this deformity. You will always find contraction or rigidity of the biceps tendon in these cases, and very frequently of the fascia lata and vastus externus, which will be more or less contracted, according to the severity of the deformity, and the length of time it has existed. These patients suffer severely from weakness of the joint, and if the deformity is allowed to proceed, are rendered at last totally unable to follow their occupations, if laborious. When it is confined to one leg, with outward curvature of the other knee, they are very liable to fall from any irregularity in the surface, and when they do so, the sensation conveyed is that of dislocation of the joint, causing the most acute pain, which will occasionally last twenty-four hours, and confine them to their bed or couch. The cast before you is an instance of this kind, and the patient was 27 years of age : I operated upon him three years since : his leg has perfectly recovered itself, and he is enabled to walk without any support. It has a perfectly natural appearance, which, even on his return home, immediately after the operation and treatment, which occupied less than a month, was so conspicuous, that inquiry was made “ if

he had had his leg removed and set straight.” He was a reporter, and originally a weaver, to which occupation he attributed his deformity, together with a spare diet. You will find in some of these cases, as I mentioned to you in younger subjects as incipient, actual lateral curvature ; which appears to come on simultaneously with the deformity in the knees, and to progress in the same ratio. We had a case some time since in the Institution of this kind ; very severe inward inclination of the knee, combined with lateral curvature, and from the patients’ account they appeared to arise simultaneously ; too much attention cannot, therefore, be paid to it in its early stage.

THE STATE OF THE POOR IN SCOTLAND*.

[ALTHOUGH the Report of the Commissioners for inquiring into the administration and practical operation of the Poor-Laws, and the Remarks of Dr. Alison on that report, are not strictly of what may be called a *practical medical* character, still these documents have appeared to us to embrace medical considerations of the very highest kind, and we have thought that a notice of them in these pages would be very much in place. The condition of the poor has important relations with disease, and therefore with the medical profession. Out of their destitution arises disease ; and the future security of the general health depends mainly upon their physical condition. We beg our readers’ best attention to the following excellent summary and comment by Dr. Somerville Scott Alison, whose name is already familiarly and honourably connected with the subject.—ED. GAZ.]

To our professional brethren in this part of the kingdom we are desirous to make known a cause in which the medical profession beyond the Tweed have nobly acquitted themselves ; and while they have done honour to themselves, have done credit to the profession at large. They have, we say it emphatically, been the zealous, the indefatigable, the humane, and the fearless guardians of their poor countrymen. No class of the community has rendered more important services to the poor, giving them gratuitous medical advice, frequently pecuniary aid, visiting their dwellings, and representing to the richer classes their wants and necessities. And this has been done while the appointed guardians of the poor, under Act of Parlia-

* Report from Her Majesty’s Commissioners for Inquiring into the Administration and Practical Operation of the Poor-Laws in Scotland. Folio, pp. 74.

Remarks on the Report of Her Majesty’s Commissioners on the Poor-Laws of Scotland. By William Pulteney Alison, M.D. Edin. 8vo. pp. 302. W. Blackwood & Sons.

ment, have wofully neglected their part, and have, to the injury of their destitute countrymen, permitted the salutary provisions of the law to fall into utter abeyance. The wretched and almost totally unrelieved condition of the poorer classes of Scotland had been pressing upon the minds of those who came most in contact with them, particularly medical men and some zealous clergymen. When Dr. Alison, of Edinburgh, whose reputation is in all the schools of medicine throughout the civilized world, and whose name for years has been associated in Edinburgh with every cause of charity and humanity, demanded the public attention, in 1839, to the subject, by a work entitled, "The Management of the Poor in Scotland." In this work Dr. Alison maintained that the poor are most inadequately relieved, that there is a vast amount of wretchedness and misery throughout Scotland, almost totally unmitigated, such as in other civilized countries has no existence.

The Sanitary Report of Mr. Chadwick, subsequently published, gave ample testimony of the destitute condition of the poor of Scotland. The facts given in these works took the English public by surprise; they had long been under the pleasing hallucination that Scotland was not merely a land of cakes and whiskey, but one of general contentment, comfort, and happiness, and above all, of boasted independence. It was a land which the world believed to be peculiarly blessed, in which there were few poor, and consequently little necessity for a legal provision. The curtain was lifted, the veil was torn aside, and destitution, grave, terrible, and pressing, was revealed—a destitution pressing down thousands to the dust, cheerless and hopeless. There were seen octogenarians, male and female, struggling to subsist upon a few pence a week; there were orphan children, neglected, boarded for the sake of cheapness with the worst and most infamous of characters; many left entirely to themselves, without even the semblance of help. Was this happy Scotland? Was this the land in which the labouring man was comfortable, too independent to accept of parochial assistance? Was this, finally, the land of religion, with its matchless clergy, the world exclaimed, with wonder and incredulity?

It was felt that the credit of Scotland's *better or richer* classes was involved; efforts were made to impugn the statements, and to throw discredit on the witnesses. Many of the lawyers, and not a few of the clergy—we say it to their shame—thus endeavoured to stifle the voice of humanity, and, having long deprived the poor of their rights, desired still longer to withhold from them that relief to which they were entitled both by act of Parliament, by religion, and common charity.

We ourselves had the gratification to afford a report to the Poor-Law Commissioners, in 1840, which we believe has proved to be useful. We told the truth as it was known to us, and, in our simplicity, dreamt not that the statement of truth could create angry feelings, though it might be unpalatable to some. In so good a cause we feared no evil: but we were soon disabused of our error. A letter arrived from a gentleman filling the office of a parish clergyman, accusing us of malice towards him, containing much personal abuse, because, he said, the destitution of the poor had been exaggerated. As proof of malice, he cited the size of a parish, as given by ourselves, which, he said, was more than double its actual extent. However, we were able to meet this proof of malice; for we assured him, which was the case, that the extent of the parish was taken from a statement in the Statistical Account of Scotland, to which his own name was attached. But as we go along we shall have abundance of the same sort of conduct. Let us, in the first place, take a cursory glance at the Act of Parliament which should have guided the managers of the poor, in order that it may be understood what were their powers, and their duties, and what are their merits. The Act in question was passed by "The Sixth Parliament halden and begun at Edinburgh, the zeir of God 1579 zeirs, be James the Sext, be the grace of God, King of Scottes, and three Estates of this Realme." In this Act there are stringent provisions against begging by all persons between 14 and 70 years of age. Thus any between these ages apprehended begging, "shall be put in the King's waired, or irones, sa lang as have any gudes of their awin to live on. And fra they have not quhairupon to live of their awin, that they be nayled to the Trone, or to other tree, and their eares cutted off, and banished the cuntries; and gif thereafter they be found again, that they be hanged." But besides containing barbarous provisions against begging, the Act specifies that "sic as necessarlie mon be susteined be almes," be duly provided for.

Great exertions were made by the landlords of Scotland, and the clergy, to prevent a Government inquiry into the condition of the poor of Scotland: it was gravely asserted that the people were exceedingly comfortable; that to give the poor a legal claim to assistance, such as exists in England, would destroy the character of the nation, remove the much-vaunted characteristic of Scotland, the independent spirit. One clergyman had the presumption or folly to assert, in a printed report, that the Scottish administration of the poor-law had attained as near as possible to a state of perfection. Notwithstanding these interested and ungenerous efforts, her Majesty's ministers di-

rected their serious attention to the subject; and in January of last year her Majesty constituted a Commission, for the purpose of inquiring on the spot into the condition of the poor, and the operation of the poor-law. The Commissioners appointed were—Lord Viscount Melville, Lord Belhaven, Henry Home Drummond, Esq., James Campbell, Esq. of Craigie, Edward Twisleton, Esq., the Rev. Patrick Macfarlan, and the Rev. James Robertson. Of these seven noblemen and gentlemen, six were Scotchmen, and one, viz. Mr. Twisleton, an Englishman.

The Commissioners commenced taking evidence in March 1843, and concluded this part of their labours in February of the present year. They began at Edinburgh, and subsequently visited different parts of the country. They had the power of summoning witnesses, and of putting them upon oath. Their mode of proceeding was to examine either the minister or session-clerk of every parish, and other persons suggested to them as likely to furnish information. The Commission also personally visited the houses of many paupers in the different districts. The Report may be divided into two parts: the 1st, containing an exposition of the administration of the law; and the 2d, in which remedial measures are considered.

We propose to give a condensed account of the present administration, as displayed in the Report, and in the evidence appended.

Persons relieved.—The persons entitled to relief under the Acts of Parliament are those who are either wholly or partially disabled, on account of age or infirmity, so as to be incapable of working and earning for themselves a sufficient maintenance,—crooked folk; sick folk; impotent folk, and weak folk; aged, pure, and decayed persons. “We find accordingly,” say the Commissioners, “that those who are broken down or disabled by old age—those who are afflicted with any disease of a permanent nature, which incapacitates them from work—those who are insane or fatuous—and children, on account of their tender years, whether they be orphans, foundlings, or deserted by their parents, or deprived of support from their father by his death, transportation, or imprisonment, are all considered proper objects of relief.” We shall presently see how far those who are thus considered proper objects of relief, are provided for.

Distributors of relief.—The distributors of relief vary according as the parish is burghal or rural. In the burghal parishes, the duty of providing funds, and of administering relief, falls upon the magistrates. In the rural parishes the duty falls upon the kirk session, and the heritors or landowners of the parish. The kirk session is an eccle-

siastical court, composed of the ministers and elders of the parish. This court should exist in every parish, but where the minister has no elders then he is supposed to represent that court, and exercise in his own person the privileges of the body. The minister is ex-officio chairman, and the elders are chosen elders by the minister. It will thus appear that the minister must be possessed of great power in this court. The heritors are members of the court. The votes of all are alike. The body, composed of kirk session and heritors, meet half-yearly, have complete control over the affairs of the poor, and may, if they deem it right, assess the parish to any amount for the support of the poor.

Funds for relief.—The primary source from which the poor are relieved is the collections made at the church doors on Sundays. In poor parishes, or where the parish church is ill attended, the collections are small. In some parishes, the heritors pay what is termed a voluntary assessment, in order to supplement the inadequate church collections. This is entirely voluntary. They do this rather than levy a regular assessment, which would be virtually binding in time to come, and because there is professed to be a great fear of breaking down the national character, by giving relief that is not entirely voluntary. In a few parishes in Scotland, chiefly in Berwickshire, the managers of the poor have levied a legal assessment, and availed themselves of the powers put into their hands for the benefit of the poor, by Act of Parliament.

Relief.—In some of the larger towns, poor-houses are found. In Edinburgh, there are three; one in Glasgow; one in Ayr; two small poor-houses in Aberdeen, one in Lanark, one in Forfar, one in Dunfermline. In several other places there are small houses for the reception of decayed persons. “The Scottish system,” say the Commissioners, is “essentially one of outdoor relief. There are various ways in which this relief is given; the most common mode is to give an allowance in money by the week, fortnight, month, quarter, or half-year. In the northern and western Highlands, generally the relief given from the poor funds is so small, that it can scarcely be taken into account, and is not represented as a material assistance, far less as a sufficient provision for the maintenance of the poor. In the county of Sutherland, we were told that it was considered ‘as an acknowledgment of poverty,’ that is, as a sort of recognition of the claim of the party receiving it, to obtain charitable aid in whatever other way he can, from the benevolent individuals in the neighbourhood. We accordingly find that in those districts the annual allowances are sometimes as low as 2s.,

and seldom exceed 10s." There is great diversity in the amount of relief given, even in those districts where it is intended as a substantial assistance to the poor.

Helpless paupers, who either from mental or bodily incapacity are unable to take care of themselves, are usually boarded with relations or friends, or strangers. Orphans, foundlings, or deserted children, are provided for in this way, and the Commissioners add, "and we may here state, that children dependent upon parochial aid are, generally speaking, well taken care of; the parties with whom they are boarded being, for the most part, persons of respectable character." It would doubtless have been better had the Commissioners directed attention to the notorious fact that many of the children dependent on, or rather receiving a pittance from, the parish, are shamefully neglected, that they are placed with persons of bad character, and that they are thrown into the veriest nurseries of crime. But we shall see by the very evidence which they produce how this important matter stands. Lunatic and fatuous persons are provided for, either by sending them to a lunatic asylum, or by boarding them in private houses; the latter, being the cheaper method, is generally adopted. Why not say at once that many are sent to the Isle of Arran, and that many are kept as no thief would keep his dog? "Quartering," the Report says, "is a mode of relief adopted in some districts in Scotland. A fit object for parochial relief is disposed of by assigning to him a particular district of the parish. It is considered obligatory on the inhabitants of that district, in rotation, to provide him with board and lodgings for a certain number of nights, in proportion to their means." There is something so remarkable in this system of quartering, so becoming in a civilized country, and so completely proving as it does how independent is the spirit of the Scottish poor, and how consistently solicitous the higher classes of Scotland, the unmitigated friends of the present mode of administration, that we are tempted to give a little of the evidence on the subject. The Rev. John Rannie, session clerk of Walls, says, "Our parish is divided for this purpose (quartering) into twelve districts. One pauper is allotted to each district, and he or she goes about from house to house, and lodges with the one or the other, as occasion requires, or he or she feels inclined. If they go round regularly, they will sleep once a fortnight in each house." The Rev. William Stevenson, of North Maveon, says, "The paupers I now refer to are boarded and lodged by the tenants; they are rather sheltered; for they have blankets of their own, which have been given them by the Kirk Session, and which they carry with them along with their bed, as

they move from house to house." Verily this is a mode of relief calculated to beget habits of regularity and of dependence upon self. Dr. Chalmers will, perhaps, see no degradation here, no risk lest the pauper be reduced to the alleged degraded condition of the English labourer. Licensed begging, we are further informed in the same Report, is another mode of relief in Scotland. The Act of 1672 directs, that if the contributions at the Parish Church are not sufficient "to entertain such persons as through age or infirmity are not able to work, they are to receive a badge or ticket, to ask alms at the dwelling-houses of the inhabitants of their own paroch only." "We find, accordingly," add the Commissioners, "that begging is, in many places, a recognised means of subsistence for paupers. In the parish of Cambelton 49 persons were in October 1842 struck off the roll, and badges were given to such of them as chose to receive them, as a license to beg."

Can this be the same system which the clergy and their patrons, the heritors, tell us is so well calculated to sustain the virtue of Scottish independence, and which is the nearest possible approximation to perfection? Truly these good gentlemen would deprive us of the use of our faculties as readily as they have deprived the poor of the means of subsistence to which they were entitled.

Occasional relief.—Allowances are sometimes made in cases of sickness or of death. These are chiefly—1st, sums paid on account of the poor when sick, in which, of course, is comprised medical relief; 2d, funeral expenses; 3d, expenses incurred by passes and removals.

Medical relief.—We have the authority of the Report, that "there is scarcely any provision for medical relief to the poor, out of the poor funds in Scotland." This seems to be left systematically to private charity. In some places, however, such relief is provided. In Glasgow there are 17 district surgeons, to each of whom twenty guineas are annually paid. In Greenock there are three district surgeons, to whom the same allowance is given.

Remedial measures.—We naturally expected that a large measure of improvement in the laws would be proposed, knowing from personal experience how great was the occasion for it. We shall in the first place consider what measures are proposed, and then offer a few comments upon them. The commissioners state that: "The points upon which we feel it necessary to animadvert, do not arise so much from defects in the laws, which provide for the relief of the poor, as from their being in many parishes inoperative, or administered in a very insufficient manner. Our object, therefore, has been to consider in what way the present law may be

made to work most efficiently, without making any very material changes either in its letter or its spirit." Why this tender dealing? Verily the law as practised has little to recommend it to favourable consideration.

Inadequacy of relief.—The commissioners are of opinion, "That the funds raised for their relief is, in many parishes throughout Scotland, insufficient." They state, that in many of these places (parishes where the only funds for the support of the poor are the church collections), it will be seen that the quantum of relief is not measured by the necessities of the pauper, but by the sum which the Kirk Session may happen to have in hand for distribution. But let us look at the evidence itself. The Rev. Dr. Gordon, Edinburgh, says, "I would say, that in general, the allowance to out-door pensioners by the charity workhouse is not sufficient to keep them in existence at the lowest possible rate of living. The Rev. J. Hunter, Edinburgh, is asked, "Could the poor of your parish possibly subsist on their allowance from the charity workhouse, without other resources?" "Certainly not." "Are you aware of the resources on which they rely?" "Public begging; and I fear that leads to lying, and stealing, and imposition on the public." "Some of them are almost absolutely famished." The Rev. J. Guthrie, Edinburgh. "Do you think the present allowances not enough?" "I think them universally deficient. In many cases, people have no choice but to steal or starve." "Do you think those small allowances tend to promote a sense of independence among the people?" "I think the very reverse."

Jos. Marshall, Esq. Leith. "In scarcely any case does a poor person receive more than a shilling a week, though utterly unable to do any thing."

Capt. Miller, Superintendent of Police, Glasgow. "The allowance is scarcely sufficient, in most instances, to pay the rent of their miserable dwellings."

Mr. D. Stowe, Glasgow. "The poor receive more from their poor neighbours than they do, or ever can, from any public charity."

Mr. Steele, Greenock. "The poor get their support more from begging than from the assessment."

Mr. J. Black, Greenock. "A resolution was come to lately, that an additional sum should be assessed for the loss which the poor would sustain, from the labouring people not being able to assist them."

Capt. Grove, Superintendent of County Police, Perth. "The poor here are a most miserable people—worse than in Ireland, where I was quartered a considerable time."

Rev. J. Menlans, Tullialan. "The number of the poor has been increasing. A

great proportion of the property of the parish pays nothing to the support of the poor at present." Witness considers, that there would be some risk to life and property, if some addition were not made to the present inadequate allowances. He has seen some cases approaching to starvation."

The commissioners, although impressed with the opinion that the allowances are inadequate, state, "That it is not desirable that there should be any appeal from the decision of the parochial managers as to the amount of allowances." They even desire to abolish the appeal to the court of session which at present exists.

The commissioners are so little instructed by experience as to fancy that due attention on the part of the managers of the poor, to the wants of this class, will be best obtained "by the influence of reason and good feeling, aided by public opinion." Are we, then, to have a new stock of reason and good feeling showered down upon the managers? Are these gentlemen all at once to become penetrated with an awe of public opinion? Have we any guarantee that the public feeling will be more operative a few years hence, than it was a few years ago?

The managers of the poor must be controlled by power more influential than reason, or good feeling, or even public opinion. Will these men, no doubt individually good men, regard such influences, having so disregarded them before? Assuredly not: they who have disregarded Acts of Parliament which they were bound to stretch to their utmost limit in so good a cause, will disregard such stimuli. We protest, in the name of an injured people, against this irreparable power. The proposed improvement, we hesitate not to aver, will end in nothing if uncontrolled power continue in the hands of interested men, and in the tools of interested men. Dr. Alison says, at p. 134, "We must always remember that all the neglect of the poor, and all the evils consequent on that neglect, which have been described, have taken place under the administration of those authorities—clergymen, elders, and appointed managers of the poor; men whose individual character is irreproachable, and who have been hitherto invested with nearly irresponsible power in this matter. It has been represented to the public even lately, since these inquiries began, that 'the interests of the poor cannot be in better hands.' I can have no wish to hurt the feelings of any of these persons by the exposure of the evils which have resulted, and still result, from their system of management; but in looking forward to the remedy which is allowed to be requisite, it is impossible to avoid drawing the inference from these facts, that if the above had been a fair description of

their conduct in most parts of the country, such evils could never have existed. What security can we have that, under the same management, the same consequences will not recur? It is impossible to shut our eyes to the fact, that, under such management in times past, the law has been so much perverted and altered from its original intention (always in favour of the interests of the rate-payers and against the poor) as to justify the observation which has been repeatedly made, on comparison of the original statistics of England and Scotland, that the difference between the two countries in regard to the aged and infirm is simply this, that the law is obeyed in the one, and disobeyed in the other."

Dr. Alison continues to say, on this most important point, "It must be remembered, also, that many of these administrators of the law have been so far from admitting, even to this day, any defect in the system in Scotland, that they formed themselves, only three years ago, into an association 'for opposing any official inquiry into the management of the poor in Scotland,' alleging that it was unreasonable and absurd to 'tamper with the Scottish poor-laws,' which were known by experience to work so well, and to produce the happiest effects on society."

We hold it to be the duty of the legislature to incite the managers of the poor to the full and fair discharge of their duties by imposing upon them the most ample responsibility. The managers should lay to their hearts the valuable remark of Mr. Chadwick:—"Every man ought, in fact, to distrust his own judgment and his own actions in the affairs of others in proportion as his interests and affections are concerned."

The Commissioners propose, that a Board of Supervision, all the members of which should be unpaid, shall be established, to which reports shall be made, at least twice in the year, from the parochial boards. They propose that the board have no title to regulate the proceedings of the Poor-Law managers, but have "the fullest power of inquiry and remonstrance." The establishment of such a board, with power to regulate the allowances of the poor, and to decide on the claims of applicants, can be of very little use for reasons sufficiently known, but on which we cannot enter.

Poor-houses.—We are glad to find that the Commissioners are sensible of the evils of boarding helpless persons and tender orphans in the houses of private persons, and that they recommend, "That, if requisite, power should be given to two or more contiguous parishes to unite for the purpose of erecting a poor-house." The following evidence will show the necessity which exists

for the erection of poor-houses. A boarding-house for paupers and children belonging to the barony parish of Glasgow:—"Two rooms, about 14 feet square each, and a third room of about the same proportions. Admitted that they sometimes have eighteen children in two rooms—eight in one, and ten in the other." Another boarding-house:—"Fourteen women and children in the house. Most of the women fatuous and very old." Another boarding-house:—"Several inmates, male and female. Maniac naked by the fire." A fourth boarding-house:—"Several idiots. One room for males, with three female idiots in it. Very much crowded."

Medical relief.—The Commissioners state that medical relief is often very scantily supplied to the poor. "They, as we have already mentioned, are often dependent on the charity of medical men both for medicine and attendance." They think it desirable "that the managers of the poor in each parish should have full discretionary power by law to afford medical relief in all cases where it may seem to them desirable." "We would further recommend, that in those parishes where it is found expedient to build poor-houses, the managers of the poor should, in connexion with the poor-houses, provide accommodation for dispensaries for the poor." On the subject of medical relief Dr. Alison says:—"I believe it to be generally deficient; where it is sufficient for them (the poor) it is a heavy and unjust burden on the medical men, who devote often, I believe, a larger portion of their time and money to the service of the poor than any other class of the community. In most towns there are dispensaries, by which medical men are relieved of great part of the expense of medicines for the sick poor; and in some of them, I believe, the duty of visiting the sick poor is very carefully performed; but being always on the voluntary principle, there is no security for its being regularly or uniformly performed." Andrew Robertson, Esq. surgeon in Gervan.—"Has practised seven years; his father has practised there fifty years, and he has a brother also a surgeon; and most of the sick poor apply to them. "Except in one or two cases, neither he nor his father ever received any remuneration from the Session, or from any other quarter, for attending the poor." William Gibson, Esq. surgeon, Dalry.—"I have practised in Dalry twenty-eight years, and have had very many opportunities of visiting the paupers. The sum which I have received from the Session, or from the Poor Committee, has not exceeded one shilling a-year. I have frequently had a difficulty in treating poor patients properly from not being able to supply them with nutritious diet. I just pay for the medicines

myself." Thomas M'Millan, Esq. surgeon, Wigton.—"Has attended the poor in seven parishes, and never got a farthing from the Kirk Sessions of any of them." The Rev. C. M'Kenzie, Ross-Shire.—"What becomes of able-bodied men who fall sick in your parish? "They are left in the hands of Providence." Much more evidence might be quoted to prove how necessary it is that medical assistance should be more adequately provided for the poor, but we greatly fear that the provisions recommended by the Commissioners will prove in a great measure inoperative. It is highly desirable that medical officers should be appointed to attend the poor throughout the whole country, with fixed salaries. We are convinced, from an intimate knowledge of Scottish parochial machinery, that until this is effected the poor at large will never be properly attended to. How useful would such a staff of well-educated and industrious practitioners prove.

In our report on the sanatory condition of East Lothian, furnished to the Poor-Law Commissioners of England in 1840, we recommended the establishment of paid parochial surgeons, and all our subsequent experience has attested the propriety of the recommendation. A body of parochial surgeons would be inestimable in relieving the medical wants of the poor, in suggesting to the lower classes the means of preserving health, and in many other obvious ways. The doors of such officers would be always open to the poor, who would not, as at present in thousands of instances, permit disease to gain a long march unchecked upon the constitution, ere relief is obtained. Modesty frequently prevents a timely application to the surgeon, and the patient delays to solicit attendance for which he knows he can offer no return, and for which no return will be made by any party whatever. Many valuable lives are in this way lost. We know this from personal experience, and the evidence of many medical men in the report of the Commissioners is to the same effect. Were medical men regularly paid for their labour to the poor, they would perform the duty with more regularity and efficiency. We trust we may not be misunderstood here: we mean no reflection on our professional brethren, whose rare devotion to the cause of neglected misery we shall ever commend; but we know that they are men, and, as such, liable to be affected by causes influencing other men. We hold it to be no sufficient argument against paying medical men in Scotland for services to the poor, that they have been found willing heretofore to act without remuneration. The question is, are their services required? Are there, or can there be provided, no funds from which

payment can be made? The services are urgently required, and funds may and can be raised for the purpose of paying for them. Again, the question might be put, does the medical man require payment? Doubtless he does. Neither in town nor country is he so over well paid in Scotland; and we know that many well-educated men throughout the rural districts, notwithstanding a life of unceasing toil, possess scarcely the wherewithal to maintain the status of gentlemen, or to purchase the necessary stock of books and instruments to maintain themselves in a state of efficiency. Doubtless the practitioner can afford to lose a sum of money as little as the heritor is unable to pay it. The parish surgeons might prove of immense advantage to the higher classes also. As appointed guardians of health, it would be their duty to investigate into the circumstances giving rise to an unusual amount of sickness or mortality. They would recommend the necessary measures for the abatement of disease, and for the prevention of its propagation amongst other classes of the community. When necessary, they would communicate with the proposed Council of Health on important points of public health. A vast body of valuable and accurate information might be obtained from these officers on the subjects of health and disease, available to the purposes of medical science and national legislation. The Commissioners, however, we regret to find are not of this opinion, and simply "think it desirable that the managers of the poor in each parish should have full discretionary power by law to afford medical relief in all cases where it may seem to them desirable." The mode in which the managers have exercised their powers is so unequivocal that we are inclined to put little trust in the exercise of discretionary power on their part for the future.

Having found that the most destitute and helpless poor required little or no help, it would be too sanguine in us to expect them to think more was required for the medical practitioner. Dr. Alison says "that much material advantage may be derived from such arrangements (the appointment of district medical officers paid by the managers of the poor), and much destitution and misery, and ultimate expense be prevented, I think cannot be doubted; but I think it equally certain that the nation can have no security for such advantages as long as the case of the sick poor is entrusted to the voluntary system of charity."

In connection with the subject of paid district medical officers for attending to the poor, we would urge the propriety of appointing officers of health. Our space does not permit of our dwelling on this point, but we beg to refer the reader to the Sani-

tory Report of Mr. Chadwick, where the subject is ably treated, and where much valuable information is collected. Another object much to be desiderated is a proper registration of deaths.

Insane paupers.—The Report informs us that “great improvement has taken place in the treatment of insanity in Scotland within the last twenty or thirty years. Most of the large towns are provided with asylums for the reception of the insane. These houses are in good order, and under excellent superintendence. But,” the Report continues, “although much has been done to ameliorate the condition of those whom Providence has laid under so heavy a dispensation, there still remains much to be done. In some of the parishes which we visited we found cases of pauper lunatics under most improper treatment.” Then follows an account of several insane persons. “Neil Gilchrist, maniac, in a dark closet, a damp earthen floor, with one blanket for his bed. No clothing but a blanket over him. Chained to the wall by a chain round his ankle.” His father has £2. 10s. from the parish for house-rent for the family. “John Livingston, a violent maniac, lying upon straw on a wooden floor, in a loft above his brother-in-law’s smithy: has no clothing on him whatever.” “Alexander Anderson, fatuous, and sometimes very violent Allowance 2s. 6d. a-week. Confined in a bed, which is boarded up so that he cannot get out. He has been kept in this way for nearly six years.” The Commissioners add, “We found a practice prevalent, particularly in the west of Scotland, of sending insane paupers to the island of Arran, and boarding them with small farmers or crofters.” At their request, Dr. Hutchinson, of the Royal Lunatic Asylum, Glasgow, proceeded to Arran, and examined into the condition of the insane paupers. The following extracts are taken from Dr. Hutchinson’s report on the subject. “Duncan Cook has two patients, a male and a female. The male patient was sent by the Barony Parish. He sleeps under the roof, on the turf covering the apartment below. He has no bedding, but some bed-clothes. The female patient has been here twelve months. She complained loudly of her treatment, which was confirmed by others. She had run away, and had been subjected to worse treatment since. I learned from several sources that a Miss M’Nab, a very old woman, formerly in good circumstances, who had been reduced to poverty, and had become insane, had been sent to Duncan Cook. In consequence of ill-usage, she ran away. She was brought back, shaken, and beaten with a stick, and shortly afterwards died. Archibald Murchie has at least eleven patients. The exact number we could not

ascertain, as every effort was made to mislead and conceal; the most distressing reports were prevalent as to his striking, kicking, and starving them. Neil M’Kenzie has two patients; in his house a man died of cold and starvation. He had no clothes, was kept in an outhouse in winter, and had a scanty supply of refuse victuals. John Campbell, about seventeen years of age, is paralytic; he has been subjected to the most cruel usage, beaten with ropes and sticks, both by M’Kinnon and his wife. Mrs. M’Kinnon attempted to deny this, but on being confronted by a neighbour who had frequently witnessed the ill usage, she could not deny it. When we were out of hearing she said she did not care a damn for what we had said; we would soon be away, and then she would work him,” [maltreat him.—S. A.] Dr. Hutchinson says, “The paupers are wretchedly fed, their diet being generally the refuse of the potatoe crop, and butter-milk; ill clad, miserably lodged, and subjected to neglect and ill usage. The patients who are confined are detained in direct violation of three Acts of Parliament. They have been sent to the island without medical certificates, and without the warrant of the Sheriffs of the county; consequently all the persons concerned in sending or harbouring them are liable to the penalty of £200, or three months imprisonment, for each offence.”

After perusing this evidence, there need no longer be any wonder expressed that the managers of the poor opposed themselves to an official inquiry, and expressed their horror of *tampering with “the Scottish Poor Laws, which were known by experience to work so well, and produce the happiest effects on society.”* Does not every right-minded Scotchman feel indignant that his poor and helpless countrymen have been thus brutally ill used? Is he not indignant that the national character has been thus foully blemished by the infamous neglect of the poor on the part of their so-called Managers? Let Scotland, would she right herself in the estimation of all humane men, insist upon better management for the future.

Able-bodied Poor.—While the right of the impotent and aged is recognised in the Scottish law, the title of the able-bodied poor to relief is not distinctly admitted, and the Commissioners state that the parochial boards are not authorised to assess on their behalf. Nevertheless, in some cases of acute illness, particularly fever, a little relief is afforded. The Commissioners are opposed to any legal provision whatever to the able-bodied men, even in times of great mercantile depression. They express their opinion “that if a paternal government give all competent facilities to the operative classes

for the more diversified extension of their industrious capabilities, and for a fuller development of self-dependence grounded on habits of reflection, it will have done all that, in an economical point of view, is, in the nature of things, likely to promote their welfare. The latter objects accomplished, we entertain an unhesitating persuasion that under emergencies of distress, as well as in ordinary times, the provisions of the existing Poor-law, supplemented, when required, by voluntary contributions, as they have heretofore been, will be found, on the one hand, amply sufficient to protect the labouring population, whether in town or country, from extreme destitution; and on the other, conducive in the very highest degree to the steady advancement of their best interests." They therefore strongly advise that the law with reference to this point shall remain unchanged. The chief ground on which this recommendation is made, is this, that the welfare of the labouring population will be best promoted by the present state of the law. Now, if it can be proved that the welfare of this class of the community can be better advanced by another mode of relief of a practical nature, and such as has been found to work well elsewhere, the recommendation of the Commissioners should not be adopted. Dr. Alison contends that the system has no advantages whatever, and that where, as in England, the opposite system is adopted, there is not only a more comfortable condition of the labouring and pauper population, but a more healthy social condition. He completely, in our opinion, demolishes the position of the Commissioners with the very evidence which they themselves have produced, and has proved to our complete satisfaction that the poor family deprived of employment are as much an object of charity as the infirm or aged, and that a legal provision is as necessary in the one case as in the other. The want of employment which overwhelms the working class in times of depression, from decrease of demand, from the bankruptcy of employers, and other causes, as completely takes from him the means of subsistence, as if for the time he were deprived of his limbs. The evil is often as unforeseen as the tempest which overtakes the mariner; it is as much an unavoidable evil as the afflictions of disease. In justice, surely the claims of the unfortunate family for legal relief are good. Has not the community had their services while they required them? Have they not, as long as they have had an opportunity, exerted themselves in their calling? Is it to be granted that they are to be allowed to starve, which experience has shewn is equivalent to support by voluntary assistance, and to fare infinitely worse than our horse, or our ass, which, when they are no longer wanted for a

season, are put out into the green pastures? Did our space permit, we would gladly quote the evidence of the Commissioners to prove how demoralising the influence of unrelieved poverty is amongst the able-bodied, how it leads to vice, prostitution, neglect of education, and the perpetration of crime itself. The evidence of clergymen, medical men, superintendents of workhouses, and governors of prisons, all lead to this conclusion.

We will here add our own testimony as to the condition of the English labouring man. It has been customary in Scotland to speak of the English labourer as a degraded being, void of spirit, and unusually free of feelings of independence thought to be peculiarly Scottish. As far as our observation has gone, the English labourer and working man is not a degraded person. We have found him possessed of proper self respect, having a sense of comfort, willing that his neighbour should be happy as himself, civil, respectful, not obsequious, thankful, gratefully so, for services. While he would rather avoid the parish authorities, he will in times of distress, in sickness, or during non-employment, make his claim in a modest, and yet manly way. He will do this rather than permit his helpless children to starve: he has the right feeling and the courage to lay aside his pride in order to serve his famishing wife and children. We know of many respectable men at this hour who have received most timely and most important aid from the parochial authorities, and who are just as independent as we could well wish to see any of our northern countrymen.

Mendicity.—"We cannot," say the Commissioners, "close our Report without remarking on the prevalence of mendicity. The evil is most observable in towns. In many of the country districts we have reason to believe that it has been checked to a considerable extent by the establishment of rural police. The law relating to vagrants is not clearly defined." They add, "and it (begging) will never be altogether abandoned until people are induced to refrain from indiscriminate charity."

Few things have appeared to us in the management of the poor of Scotland more unreasonable and cruel than the practice of putting down mendicity by the rural police. While a mere shadow of relief is afforded to the poor, it is most unjust and inhuman to take from these wretched persons the opportunity of obtaining that relief which charitable neighbours are willing to grant. When adequate relief is given, so as to prove a real and substantial subsistence, then it might be practicable and proper to suppress vagrancy; till then it is inhuman cruelty. We are at a loss to conceive how English blood, though in the veins of a poor man, even of an unrelieved poor man, does not boil

with indignation, and incite to acts of resistance and outrage, when in his person the liberty of the subject is thus invaded. We know it, that the poor of Scotland are the victims of a brutal un-English tyranny. The rural police, whose services have been noticed by the Commissioners with obvious approbation, exercise a fierce despotism against those helpless beings. We remember well with what unfeeling pleasantry one of the rural police informed us that he had at last detected "the fellow begging; that he would never try it here again, for he had had him in the 'lock up' all night, without fire or food, and had carried him in the morning to the boundary of the parish." It cannot be denied that many of the unrelieved poor are actually hunted from parish to parish in the most cruel manner: even sick persons are moved about in this way, and the evidence gives a case in which one person actually died during her forced peregrinations. The superintendent of police in Roxburghshire unconsciously testifies against the cruel usage of the poor. "Witness has gone round to the farm houses, and got the masters to agree neither to serve nor to harbour vagrants; but then their wives scout him, and tell him that they are in the will of God Almighty,—and that as long as they have a handful of meal or a pickle of straw, they will not turn the beggars from the door."

It cannot be the object of the managers of the poor in Scotland to destroy every good trait amongst their countrymen. They will neither give nor let give, yet they assure us the great object they have in view is to elevate the character of the people. Not satisfied with rendering the poor, miserable beggars, miscreants, and criminals, would they destroy the very virtue of charity, even amongst women—a virtue which their theories make it a point to foster. It is gladdening to observe, despite the efforts of police, that Scotch women will still be charitable, and share with women in the savage state that heaven-born trait so well described by the poet of the poor—

"Man may the sterner virtues know,
Determined justice, truth severe:
But female hearts with pity glow,
And woman holds affliction dear."

We would venture to add—

"Be't woman's sacred part, to fill,
With hope, the fainting beggar's breast;
The 'pickle straw, the handful meal,'
To give him—hunted and oppress."

Mr. Chadwick speaks to the point. He says:—"To refuse relief, and, at the same time, to punish mendicity when it cannot be proved that the offender could have obtained subsistence by labour, is repugnant to the common sentiments of mankind."

To sum up—doubtless the Commissioners

have had a difficult task imposed them. Yet they had a noble opportunity to have befriended the poor of Scotland. We regret we cannot say that they have fully availed themselves of it. Doubtless with the best intentions in the world, these honourable men, for whom we have the highest regard, have failed in their purposed remedies. They have gone only part of the way; even their recommendations, as far as they go, will to a great extent prove ineffective, if not enforced by the usual terrors of the law. In the meantime we thank them for their services in the cause of humanity. We know the difficulties they have had to contend with,—a body of heritors and of clergy devoted to the present system. We trust that the wisdom of parliament will meet the wants of the Scottish nation. It is but justice to one of the Commissioners, Mr. Twisleton, an English gentleman intimately acquainted with the administration of the Poor Law in England, to say that he dissented from the report much on the grounds which have been advanced against it by Dr. Alison and ourselves. We feel deeply indebted to Mr. Twisleton. He is not the first Englishman who has befriended Scotland, and we trust that his example will be followed by many of his countrymen in the British Houses of Parliament, and that by their means the hands of Scotland's friends may be strengthened and enabled to do justice to the poor.

Of Dr. Alison's work it is scarcely necessary for us to say a word in praise. It is almost enough, in order that it be prized, that it be known as his. We earnestly recommend a perusal of it by all friends of Scotland, by all friends of humanity. It is the fearless and able advocacy of the cause of the poor, by a man who has for them, a heart to prompt, a head to guide, and a hand to give.

S. SCOTT ALISON, M.D.

Member of the Royal College of Physicians,
London.

THEORY OF RESPIRATION.

By GEORGE KEMP, M.D. Cantab.

Fellow of the Cambridge Philosophical Society.

(For the Medical Gazette.)

THE object of the following paper is to connect the principal facts of the phenomena of respiration, as elicited by trustworthy observers, and to offer a new and independent mode of accounting for the results of that process.

It is taken for granted, as an axiom never to be infringed, "that experiments so constituted as to ensure the

greatest practical simplicity in their conditions, and at the same time to establish general principles, cannot be set aside, or even invalidated, by such as involve numerous stages, each one of which is exposed to known sources of error, and which, after all, are only calculated to prove a particular case."

Considerable difficulty has arisen from the very discrepant results obtained by Lavoisier and Séguin, as compared with those of Menzies, Davy, Allen, and Pepys; and the cause of this difficulty seems principally to have originated in the pre-conception, that the function of the lungs is carried on with uniform intensity. Dr. Prout did much to reconcile the statements of previous philosophers, by showing, that the quantity of carbonic acid given off, and consequently, of carbon oxydised, appreciably differs at different periods of the twenty-four hours; and, in a most valuable summary of recent researches published in the *Chemical Gazette*, No. 38, p. 154, we are put in possession of important average observations, which, when taken in connection with other independent facts, will, if the writer mistakes not, place the subject in a much clearer point of view than we have hitherto enjoyed.

It will be remembered, that two modes of investigation have been adopted to solve the problem of respiration: the one, by deducing the quantity of carbon consumed from the quantity of carbonic acid given off by the lungs; the other, by comparing the whole amount of carbon received as food into the animal frame with the carbon conveyed away with effete matter, gave the difference as expressive of the quantity of the carbon removed by the respiratory organs. The latter plan has been adopted by Dalton (whose results do not remarkably differ from those obtained by the former mode), and more recently under the direction of Professor Liebig, the results of which differ so widely and essentially from all the others, that they cannot be rendered available; nor will a practical man have any difficulty in discovering that the whole plan was ill devised, as known sources of error exist at each one of the numerous stages of operation.

Here are, for instance, six different substances to be analysed—bread, potatoes, meat, lentils, pease, and beans;

and every candid person must acknowledge, that the most carefully conducted elementary analysis is subject to appreciable error: we have, therefore, six chances of error to begin with: if the quantity of water in each was estimated by a separate operation, as was the case in the bread, the chances of error amount to twelve; again, these bodies are not definite chemical compounds, but mere mechanical mixtures differing in every part; still further, the portions used for analysis formed but a very small part of the whole. The results obtained, for instance, as the composition of bread were doubtless true, for the three or four hundred milligrammes used for analysis, but cannot be assumed so for 27,936 ounces which were consumed.

These remarks are by no means made in a spirit of hypercriticism, but as an apology, if such can be needed, for not receiving results thus obtained, in opposition to those of the highest authority, by means of other modes which do not participate in so many sources of error.

But, whatever may be thought of Professor Liebig's statements, his reasoning on the respiration is still more unfortunate, as it involves the palpable absurdity, that the part is greater than the whole; that the quantity of oxygen contained in a certain portion of carbonic acid is greater than the quantity of carbonic acid itself: thus, at p. 13, we read:—"If we assume, with Lavoisier and Séguin, in order to obtain a foundation for our calculation, that an adult man receives into his system daily $32\frac{1}{2}$ ounces (46,037 cubic inches = 15,661 grains, French weight) of oxygen," &c. &c.

Now, Lavoisier and Séguin estimated the carbonic acid exhaled from the lungs in twenty-four hours at 8584 grains, or 17,9 ounces, which are equivalent to 13 ounces of oxygen, not $32\frac{1}{2}$ ounces. But the fact is, that the whole table at page 283, note 1, is false, as any person acquainted with the fact, that the volumes of carbonic acid and the quantity of oxygen it contains are so nearly equal as to be considered so in all approximate calculations, will see at a glance. In this table the volume of oxygen is in the first line made more than three times that of the corresponding carbonic acid, and in lines three and four, the smaller quantity of

carbonic acid contains more oxygen than the larger.

Having thus removed the principal stumbling-block from our path, we at once proceed to offer an independent mode of solving the problem of respiration, and then to test its accuracy by the observations of others.

Assuming, as in a former case, that the chyle contains in itself all that is necessary for the fresh deposits in the animal body, whether tissues or fat, it is clear that the sum of the elements of the new deposits will accurately express the sum of the elements of the chyle, however the molecular arrangement of the two may differ; it is also clear, that provided we are able to collect all the ultimate products into which the new deposits resolve themselves, the sum of the elements of these products will also be accurately represented by the sum of the elements of the new deposits: it will therefore be granted, that the original formative body, the chyle, and the ultimate products are legitimate subjects of comparison, and that the sum of the elements of the one may be taken as expressive of the composition of

the chyle + 10 equi. of water = $C_{58} H_{43} N_5 O_{21} + 10 HO$
 $= C_{58} H_{53} N_5 O_{31}$
 $= (C_{53} H_{38} O_{21}) + 5 \text{ equi. of carbonate of ammonia.}$
 (A) and $(C_{53} H_{38} O_{21}) + 123 O = 53 (CO_2) + 38 HO$.

In order, therefore, to convert the whole of the chyle into the ultimate products obtained from the lungs, skin, and kidneys, 123 equi. of oxygen are

$C_{58} : O_{123}$; but $C_{58} = 58 \times 75$; and $O_{123} = 12300$;
 $= 4350$

therefore the ratio $C_{58} \quad 4350 \quad 1$
 $\quad \quad \quad O_{123} \quad 12300 \quad 2,82$

Again, the chyle = $C_{58} H_{43} N_5 O_{21}$
 $= (C_{57} H_{41} N_4 O_{20}) + \frac{1}{2} \text{ equi. of urea} = (C_1 H_2 N_1 O_1)$
 $= (C_{57} H_{29} O_{20}) + 4 NH_3 + \frac{1}{2} \text{ equi. of urea.}$
 (B) and $(C_{57} H_{29} O_{20}) + O_{123} = 57 CO_2 + 29 HO$.

Again, therefore, we require 123 equivalents of oxygen to convert the body remaining, after the elimination of urea and ammonia from the chyle, into carbonic acid and water.

We therefore assume, that the quantity of the carbon in the urea secreted, is to the oxygen obtained by respiration, as C : O_{123} , or 75 : 12300, and to the whole amount of carbon in the chyle as 1 : 58. The practical observations of others agree well with this hypothesis, as will be seen in the

the other. Now the ultimate products of the disintegration of animal bodies, may, in a practical point of view, be confined to urea, carbonic acid, and water. It is true that we are unacquainted with the composition of the peculiar fatty matter secreted by the skin; but this is so small a quantity, as compared with the others, that it may be practically neglected, and will, even with the addition of organic elements which separate from the body in the form of hair, nails, &c. be found to involve but a very small fractional error in calculation. The problem, then, to be solved, resolves itself simply into establishing the relation between the sum of the elements in the chyle, and those which pass out of the body in the form of urea, carbonic acid, and water. As a preliminary step, we proceed to determine the quantity of oxygen necessary to resolve the elements of the chyle into the above three bodies; or, as urea may, by the mere addition of the elements of water, be converted into carbonate of ammonia, into the three binary forms, carbonic acid, water, and ammonia; thus—

necessary: the ratio, then, of the carbon taken in the food to the oxygen obtained by the act of respiration is—

sequel. With reference to the quantity of carbon consumed, the tables of Andral, Gavarret, and Scharling, as given in the Chemical Gazette, p. 156 and 157, 1844, are made use of, as they contain a summary of no less than 90 observations, on different persons, at various ages, made by night as well as day. For the quantity and analysis of urine, the tables of M. Alfred Becquerel are referred to, as these have obtained the sanction of the very extensive clinical experience of Dr. Prout and

Dr. Golding Bird: they are recorded in Dr. Prout's work "On Stomach and Urinary Diseases," p. 519, last edition.

According to the tables on respiration, it is stated, that the average of carbon expired per hour, after corrections for moisture, is 11,2 grammes; the maximum, according to Brunner and Valentin, 11 grammes; but a small portion of carbonic acid is also exhaled by the skin (Dalton estimated this quantity at $\frac{1}{4}$ of an ounce per diem): we shall be perfectly safe, then, in assuming the quantity of carbon given off per hour, by lungs and skin, as 11,2 French grammes; this, for the twenty-four hours, amounts to 8,64 English ounces. If, then, there be any truth in the statement above, that the carbon in

226,802 grains + 146,467 grains = 373,269

= 0,77 of an ounce,

but urea = $C_2 H_4 N_2 O_2 = 754$,
and $C_2 = 150$,

therefore the amount of carbon contained in urea is as 150 : 754,

or 1 : 5;

and therefore the quantity of carbon in the urea = 0,77

5

= 0,155 of an ounce.

We have also seen above, that the quantity of carbon, calculated on hypothesis, is 0,148 of an ounce; a coincidence which is remarkable, and calculated to give some confidence in its truth.

The pathologist will now trace the connection between diminished action of the lungs, as in "phthisis pulmonalis," and the tendency to secrete an abnormal proportion of lithic acid, when compared with the urea; he will also see why, in cases of excessive secretion of urea, the quantity is greater during the night than the day, the intensity of respiration during the day being to the night as 1,24 : 1. It is evident, that in the latter disease one of two things must happen; either the intensity of the respiration must become inverse to the disposition to form

$(C_{57} H_{29} O_{20}) + O_{123} = \{C_{57} H_{20} O_{20}\} + H_9 + O_{123}$
 $\{C_{57} H_{20} O_{20}\} + O_{114} + 9 \text{ equi. of water.}$

And this agrees with the universally acknowledged fact, that the volume of CO_2 given out never equals that of the oxygen inspired; and the above formula shows that, from the very nature of the case, it never can.

Now, on comparing the quantity of

$C_{58} : O_9 :: 4350 : 900$

and 4350 : 900 :: the whole quantity of carbon

eliminated

: 8, 64

: the deficient quantity

of oxygen

: 1,78

the urine is to that of the chyle as 1 : 58, the quantity of the former is, by calculation, $\frac{8,64}{58} = 0,148$ of an ounce, and this is well borne out by Dr. Prout's tables: thus, 35 fluid ounces of urine, sp. gr. 1020, passed in twenty-four hours, contains 226,802 grains of urea, and 146,467 of other organic matter, in combination with ammonia. Professor Liebig and Dr. Enderling have recently denied the existence of lactic acid in urine, but, whatever this small portion of organic matter may be, the circumstance of ammonia being present renders it perfectly safe to consider the ammonia compound as represented by the formula for urea. Now,

urea, or emaciation must result from the rapid elimination of tissues.

But there is another point to determine. On comparing the formula for the chyle with the quantity of oxygen obtained by respiration, we find an excess of this element; thus, C_{58} requires only 116 equivalents of oxygen, while both my hypothesis and the facts of the case arrive at 123 equivalents; how, then, is this excess of oxygen disposed of?

On referring to equation (B) it appears, that of the 29 equivalents of water supposed to be formed during the process of elimination, 9 must be formed into water, at the expense of 9 out of the 123 equivalents of the oxygen furnished by the respiratory process. Thus,

oxygen thus absorbed, by hypothesis, with the whole quantity of carbon contained in the chyle, we arrive at as near an approximation as we can possibly expect to the quantity of oxygen actually found by direct experiment to have disappeared, for

But the quantity of oxygen required to convert carbon 8,64 ounces into CO_2 is 23,04; the whole amount of oxygen inspired is, therefore, 24,82, and Brunner found, as an average of twelve experiments, that the volume of oxygen inspired was to the volume of carbonic acid formed as 4,720 : 4,356; the deficiency is therefore 0,364; which is also confirmed by Professor Valentin's mean of twelve experiments; and on comparing this with the whole quantity of oxygen, according to the experimental data, we have 4,720 : 4,356 :: 24,82 : 1,9, having obtained 1,78 by hypothesis.

Nor does this theory fail to assist us in the remarkable case of carnivorous animals. It has been seen above, that the quantity of oxygen which dis-

$\text{C}_{5.8} \text{H}_{4.3} \text{N}_5 \text{O}_{2.1}$ becomes $(\text{C}_{5.8} \text{H}_{4.3} \text{N}_5 \text{O}_{2.1}) - (\text{C}_5 \text{H}_1 \text{N}_3 \text{O}_5)$
or $(\text{C}_{5.3} \text{H}_{3.3} \text{O}_{1.6})$ $- 2\frac{1}{2}$ equi. of urea.

Now, to convert $\text{C}_{5.3} \text{H}_{3.3} \text{O}_{1.6}$ into carbonic acid and water, 123 equiva-

$\text{C}_{5.3} \text{H}_{3.3} \text{O}_{1.6} + \text{O}_{1.23} = \text{C}_{5.3} \text{H}_{1.7} \text{O}_{1.23} + 16$ equi. of water.

We have, therefore, a demand for an excess of 17 equivalents of oxygen, instead of 9. This is only one of many modes of showing that an excess of oxygen involves an excess of hydrogen to be oxydised, and has been selected as the most simple case; but others are sufficiently obvious. By referring to the analysis of the urine of the lion, tiger, and leopard, by Hieronymus*, it will be seen that this fluid contains 13,2 per cent. of urea; the average of human urine only 1,4 per cent.; the hypothetical assumption is, therefore, fully borne out by fact.

It will now be necessary to examine Professor Liebig's views with reference to the bile, as an agent in respiration, which are, however, from beginning to end, so contrary to analogy and fact, that were they not extensively circulated, they would not be worthy of serious notice. The whole error has arisen from a want of practical knowledge of the subject, and a very partial record of the testimony of others. At page 64 of his "Animal Chemistry," he has stated, on the authority of Burdach, that man secretes daily 17 to 24 ounces of bile; a large dog, 36 ounces; a horse, 37 lbs.; now, on referring to Burdach, it will be seen that he merely

appears in man during respiration is, according to Brunner and Valentin, $\frac{1}{13}$ of the whole amount; Dulong also found it about $\frac{1}{10}$; but in carnivorous animals the loss was as much as $\frac{1}{5}$ to $\frac{1}{2}$; it is evident, then, that however the law of the diffusion of gases may explain the phenomenon in graminivorous mammals, here it utterly fails. In the theory of the bile I deduced a formula for the chyle, from the analyses of Marcet and Macaire, which proved the remarkable fact, that this primoformative body is represented, both in carnivorous and graminivorous mammals, by the same formula, $\text{C}_{5.8} \text{H}_{1.3} \text{N}_5 \text{O}_{2.1}$; and by supposing that the whole of the nitrogen is eliminated in the form of urea,

lents of oxygen are required; thus—

quotes the opinion of Schultz, as deduced from most exceptionable experiments, in order to controvert them; which he does by a most masterly "reductio ad absurdum." "Sollte nun," says Burdach, "ein Ochs eben so viel Speichel wie nach Schultzen's Meinung ein Pferd, nämlich 10 Pfund, secerniren, so würden diese beiden Secretionen allein, binnen 24 Stunden so viel betragen als die gesammte Blutmasse."

But we have no occasion in this instance to resort to analogical reasoning, as we possess facts of a most determinate character for our guidance. It has already been shown, that the bile, from its composition, is most probably destined for a much more important object than merely to re-enter the system in order to be eliminated in the form of carbonic acid and water; it has also been shewn, that the food of all animals contains one portion, which absolutely requires to be combined with a body consisting of the same elements, in precisely the same proportion as the bile, before it can be converted into chyle. In a paper, which will shortly appear, on Digestion, Assimilation, and Nutrition, it will be proved, from the noble researches of Boussingault, that the whole of the bile which can be supposed to be secreted is necessary for the conversion of the non-azotised portion

* Lehrbuch der Chemie, von J. J. Berzelius, neunter Band, S. 460.

of the food into the nutrient fluid; and those who have made direct experiments on the subject, know well that the bile, when perfectly freed from mucus, and exposed to a moderate temperature and atmospheric air, is not disposed to give off its carbon in the form of carbonic acid, whereas fibrine or blood, submitted to the same conditions, eliminates its carbon in the usual binary form with the greatest facility: the bile is, in fact, by no means suited for the production of carbonic acid in the way alluded to, while the fibrine is eminently so.

Without attaching undue importance to the above views; without presuming to think that subsequent discoveries may not render some modification necessary; and above all, without in the slightest degree interfering with that broad line of demarcation which sound philosophy will ever interpose between what *may be* and what *really is*; the writer believes, that many portions of the above reasoning will be considered as near an approach to demonstration as moral evidence admits of, and that this theory accounts more fully and satisfactorily for the facts of the case, than any other which we at present possess.

The principal points of the above paper may be summed up as follows:—

1. That respiration, urinary secretion, and exhalation, so far as it regards the moisture formed by the excess of hydrogen in the matters eliminated, stand in a certain determinate relation to each other; and this relation is such, that if one of these functions vary in intensity, the others will vary also, either directly, and in that case the elimination of tissues becomes increased in proportion, or inversely, in which case they may be considered as mutually compensative.

2. That the excess of oxygen absorbed, with respect to volume, over the volume of carbonic acid exhaled, is fully explained by the circumstance that the quantity of oxygen in the effete matters is not sufficient for the oxidation of the hydrogen. The theory, however, does not suppose that this change is confined to any one part, the lungs for instance, but occurs in every portion of the animal frame in which the elimination of effete matters takes place through the agency of oxygen.

3. That the same laws, both of orga-

nization and dis-integration, are observed in graminivorous as carnivorous mammalia, and that these laws act under precisely similar conditions; nor is it necessary to suppose that in the former class of animals the non-azotised portion of the food affords carbon for the production of carbonic acid in the lungs: nor is it consistent with structural or physiological facts, that any part of the amylaceous portion of the food is converted into carbonic acid before its assimilation and adaptation to some part of the animal frame. The carbonic acid is, in fact, as much the result of elimination of effete matter in the one class of animals as in the other.

4. That neither is the bile a source of carbon for the lungs, as it is not adapted for the elimination of that element under the conditions which are present, viz. under the influence of moderate heat, oxygen, and moisture, but is required for the assimilation of the non-azotised portion of the food.

5. That these theoretical deductions are borne out by chemical and physiological observations, so far as carnivorous and graminivorous mammalia are concerned. The biliary fluid and chyle of serpents and birds not having been examined, we are clearly without the data for explaining the process of respiration, as it occurs in their cases.*

Douglas, Isle of Man,
Oct. 29, 1841.

* As this paper may fall into the hands of those who entertain a justifiable degree of jealousy at any expressions assuming a mathematical form, which are not adapted to strictly mathematical treatment, it may not be amiss to subjoin, that, in reasoning on the interchange of elements in organic bodies, the sums and differences alone of the elements are regarded, and thus the expression $C_{58}H_{43}N_5O_{21}$, for example, implies merely, that the chyle is composed of these elements in the proportions stated, in a certain molecular condition essentially differing from their mere addition: the formulae, $N+O$ and NO , equally well express the presence of nitrogen and oxygen in the ratio of their equivalents, but the one represents atmospheric air, a mere mechanical mixture; the other, protoxide of nitrogen, a chemical compound. In reasoning of this kind, compound bodies are considered as disintegrated, and the numbers expressing the equivalents of each element are then used as co-efficients, nor can these conventional formulae, as universally adopted in Germany, occasion any confusion, as they differ from any known mathematical expressions. The exponential mode of expression as used in France, should undoubtedly be abandoned; the formula $(H+O)^n$, leads instinctively to expansion by the binomial theorem, producing a series of compounds which would astonish most chemists.

ANALYSES AND NOTICES OF BOOKS.

“L'auteur se tue à allonger ce que le lecteur se tue à abrégé.”—D'ALEMBERT.

Medico-Chirurgical Transactions, published by the Royal Medical and Chirurgical Society of London Vol. the XXVIIth; of New Series vol. the XIXth. London, 1844.

THERE are usually phases in the life of learned societies as well as in the life of man. They are weak at first, or they are strong; but, in either case, they are generally instinct with power, so that the weakness will often grow into strength, the strength will advance to lusty manhood. By and by, however, the spirit that seemed to animate them flags; as in a tree, the fruit-bearing boughs of earlier periods become old, and cease to put forth blossoms, or they are pruned away one after another, until by the time that a single generation of men has run its course, the tree often stands there with nothing of its original parts about it save the trunk; and the trunk, we know, though indispensable, is yet the least essential portion of the tree; for strip the trunk of all its buds, it will inevitably die, whilst each individual bud, set by itself, or grafted on another stem, will rise up an independent plant.

Even so it is with learned societies; they have their periods of vigour in the majority of instances, and then they have their periods of decline. It is not often that they oscillate betwixt strength and weakness, betwixt growth and decay. Yet they do sometimes, and the causes, or assignable causes, of each estate, vary in different cases. Sitting still too long in one place has occasionally seemed the most potential cause of decay; and again, removal from the original soil has seemed to bring the blight. But in other and more fortunate instances removal has appeared to exert the happiest influences. The Royal Medical and Chirurgical Society is one of those which has pursued the tenor of its way pretty evenly, on the whole; it has had its periods of splendour and of more moderate lustre, but it has never suffered anything like a total eclipse. The Society had rather languished for some years in Lincoln's Inn Fields; the necessity for a westward move, which may be

called the natural course of society as well as of the sun, had for some time been felt, and after long and anxious search for a house, the one in Berners Street was found, and the Society removed thither, we forget how many years ago—some ten or twelve at least. This event was a new epoch in the Society's prosperity; the meetings were soon better attended than ever they had been in Lincoln's Inn Fields; new members began to come in in shoals; the funds, from being somewhat crippled, became prosperous; the volume of Transactions, instead of being a burthen, proved a source of revenue; and under the brilliant presidencies of Dr. Bright and Sir Benjamin Brodie the Society may be said to have reached its acmé. Let it not be forgotten, however, that it was under the presidency of Dr. Elliotson, in 1835, that the grand start in the prosperity of the Society's affairs was made. In the joint names of John Elliotson, Doctor of Physic, Sir Astley Cooper, Bart., and John Yelloly, Doctor of Physic, a petition was presented to His Majesty King William IV., praying for a Charter of Incorporation for the Society, which was most graciously granted on the 30th of September, 1835, since which time the Society has had the prefix of Royal, and the members have been designated Fellows. The printed list of members in this year occupies about fourteen pages; the list in the volume which has just appeared takes up as many as twenty-eight pages,—an extension from which the augmented prosperity of the Society may be surely inferred. It is with great regret, however, that we perceive the name of Dr. Elliotson withdrawn from the list of Fellows; the benefactor of the Society, as its active officer, and for many years the unwearied contributor to its Transactions, ought still to be found on its roll. The unhappy and much-
vexed question of mesmerism was, we believe, the cause of Dr. Elliotson's secession from the Society.

Contemporaries, and parties near at hand, judge of societies by the attractions they present at their public meetings; posterity, and those at a distance, form their estimate from the contents of the published volumes of Transactions. During the earlier period of the Medico-Chirurgical Society's existence, it was by no means held necessary to

publish a volume every year. One in two, or sometimes even more, sufficed to embrace everything that was deemed worthy to see the light under the ægis of the Society. Of late years the Society has felt it a duty to publish every year. Of course, when very rigid selection is made, the article may be presumed to come out more intrinsically valuable; and it is unquestionable that the earlier volumes of the Transactions of the Medical and Chirurgical Society will for ever remain monuments of the activity and discrimination with which medical science was cultivated in England during the period of their appearance. But we are by no means disposed to be the laudator temporis acti,—to find nothing good or praiseworthy that is not covered with the rust of time; on the contrary, we always hail these volumes of the Royal Medical and Chirurgical Society as precious land-marks in the onward course of medical experience; and greatly prefer the average samples they afford each year, to the picked specimen they would present did they only appear at intervals of two or three years.

Abstracts of all the papers contained in the present volume have already appeared in our pages, and for the major part some account of the discussion which usually follows the reading of a paper at the Society. We shall therefore do no more than give an abbreviated catalogue of the contents of the volume, by way of remembrancer, or finger-post, to our readers.

Cases of Rupture of the Ureter or Pelvis of the Kidney from violence, by Mr. Stanley. A Case of Cysticercus Cellulosa of the Brain, by Mr. Otley. On the presence of Spermatozoa in the Fluid of Hydrocele, by Mr. Dalrymple. Cases of Carcinoma of the Thyroid Gland, by Mr. Caesar Hawkins. On the Admission of Air into Veins, by Mr. Bransby Cooper. On a Horn developed on the Human Skin, by Mr. Erasmus Wilson. On the Early Organization of Coagula, by Mr. Dalrymple. Case of Extirpation of Ovarian Tumor, by Mr. Greenhow. On the State in which Uric Acid exists in the Urine, by Dr. Bence Jones. Case of Carcinoma of the Lungs, by Dr. George Burrows. On Acute Diseases of the Larynx and Trachea, cured by Tracheotomy, by Dr. J. A. Wilson. On the Presence of Oxalate of Lime in the

Urine, by Dr. Jones. On Obstructions of the Branches of the Pulmonary Artery, by Mr. Paget. On the Composition of the Meconium, by Dr. Davy. On Paracentesis Thoracis, by Dr. Hamilton Ree. Case of Empyema, by Dr. Theophilus Thompson. Omental Sacs in Hernia, by Mr. Hewett. Case of Dissecting Aneurism of the Aorta, by Dr. Todd. Case of Aneurism of the External Iliac Artery, in which the Internal Iliac was tied, by Mr. Hey, York. Cases of Tubular Expectoration from the Lungs, by Dr. Reid. A Tabular View of the Seat of Tubercle in 180 Cases, by Dr. P. H. Green. Case of Tumour of the Right Hypochondrium, with Evacuation of Biliary Fluid, by Mr. Barlow. Case of Gelatiniform Cancer, by Dr. Warren, U. S. Examination of a Cyst containing Seminal Fluid, by Mr. Paget. Records of Progress of Asiatic Cholera, by Dr. S. W. J. Merriman. Case of Necrosis of the Lower Jaw, by Mr. Sharp, Bradford. On Mollities Ossium, by Mr. Solly. Case of Fistula between Bladder and Ileum, by Mr. Worthington. On the Recorded Cases of Operations for Extraction of Diseased Ovarian Tumours, by Mr. Phillips.

MEDICAL GAZETTE.

Friday, December 6, 1844.

“Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tuæ; potestas modo veniendi in publicum sit, dicendi periculum non recuso.”

CICERO.

THE DILEMMA, AND REMEDY THE SECOND.

ASSOCIATION OF THE GENERAL PRACTITIONERS INTO A DISTINCT COLLEGE, INCORPORATED BY ACT OF PARLIAMENT, HAVING AN ELECTIVE COUNCIL, A COURT OF EXAMINERS, AND POWER TO FRAME BYE-LAWS, AND TO EXAMINE AND LICENSE ALL FUTURE GENERAL PRACTITIONERS*.

WE began with the College of Physicians as the means of helping us in our present difficulties, that being the chartered body which has the first claim to consideration from its antiquity, which has about it the highest

* Vide Marylebone Manifesto, p. 12.

prestige (to be guilty of using a French word), and which would, as we apprehend, most effectually aid the medical profession with the public, place it higher in general estimation, and raise the character of the mass of its constituent members—to say nothing of the great accession of influence and of wealth, of wealth and of influence, that would be gained in this way by the College. Association of the general practitioners with the College of Physicians, we are clearly of opinion, would be the best thing for all parties—for the profession and for the public.

The next best thing that could be done, in our apprehension, would be the association of the mass of the profession with the College of Surgeons. This institution is rich, is influential; always numbers the leading members of the surgical arm of the profession in its Council and Court of Examiners, and occupies a large space in the public attention. Its noble museum and copious library give it a farther and powerful hold upon professional sympathies.

Our views upon this subject are already well known: we believe that the union would readily have been—could still readily be—effected, to the immediate cementation of all differences, to the instant assuagement of all angry and discordant feelings. There would then be an united and most powerful medical profession, with the College of Surgeons for its head instead of the College of Physicians; this would be the only difference. Our plan for bringing about this union would simply be, to draft in as Fellows or Associates of the College, and give a voice in the election of the Administrative Council to, all who had been members for five or ten, or any intermediate number of years; those who are now members, and have been so for a smaller term of years than that determined on, to be received as

Fellows or Associates on attaining the prescribed standing.

The exception we would make—and even this would be a kind of straining of authority—would be based on the ground that as it was the *profession* of surgery, or of medical surgery, which was to be represented, and not the traffic in drugs and chemicals, so no one should be admissible to the rank of Associate or Fellow who kept an open shop, or had his window ornamented with red and blue bottles, who sold Daffy's elixir, and the best Windsor soap, &c. The stipulation should be, that the medicine room should be strictly private.

This we apprehend is the arrangement that would give greatest satisfaction to the general body of the medical practitioners of England, almost every man among whom of any name or influence is a member of the Royal College of Surgeons. This too is the union for which the members of the College of Surgeons have been contending ever since we remember the subject of Medical Reform, in anything of its present shape, discussed in London; it is that for which meetings were held at Freemason's Tavern, in 1828, we think, and which has been smouldering ever since, though breaking out at intervals only into a fitful flame; it is that which, when we look at our brethren as composed of Englishmen, we must suppose can never be given up, until it has been granted; though when we see them in their professional capacity, we are rather more inclined to doubt and despair; for there is, in truth, a sad lack of independent feeling among us: defective elementary education it is which always makes the great mass of the medical profession the slaves in some sort of the leading medical, and especially of the leading surgical, practitioner of the day.

So much by way of preface to the subject of our text: THE ASSOCIATION

OF THE GENERAL PRACTITIONERS INTO A SEPARATE COLLEGE. We are clearly of opinion that this proposition is a false step on the part of the leaders of the great body of the medical profession. The thing is not only against the views and prejudices of the community, but also of the medical profession itself. A College of general practitioners in the present day, incorporated by all the Royal Charters in the world, would never have more of public weight and authority than any private Medical Association—the Royal Medical and Chirurgical Society, for instance, or the Medical Society of Bolt Court. Supposing this College of General Practitioners to have wrung by force of right and respectability, and on the ground of refusal of other corporate bodies to receive them, a Charter of Incorporation from Government, and even the right to examine and license the future general practitioners, our conviction is that they would still be very little farther forward than they are at the present moment. A diploma, being a mere certificate of competency,—and we presume that the College of General Practitioners could never aspire to grant more than this,—is a totally different affair from a diploma that confers a degree or title, such as that of Doctor in medicine. The public do not ask whence the title came, seldom how it was obtained; it commonly passes current unquestioned; and even if questioned, and it be found of Giessen or Erlangen origin, it is little less thought of than if it had been won by long years of study at the alma mater which accords it, and of searching examinations successfully passed. The title-conferring diploma suffices, then, and goes unquestioned under any circumstances. Not so the simple certificate of competency. That is valuable only as it has been granted by men who are themselves acknowledged competent, whose names

are familiar to the world, and who have reputation in the republic of letters and science as well as of practice. But such names a College of General Practitioners cannot at this time, and probably never could, command. Why are not the practitioners of England content with their license from Apothecaries' Society? It is all they require to have in law; it is sufficient to start upon in so far as qualification goes; but it has not the weight, because 1st, it confers no title, and 2d, because it is given by men who, however respectable and esteemed by their own immediate circle of friends, are utterly unknown to fame. Who, in fact, ever prided himself on his certificate from the Apothecaries' Society, and in what department of the public service is it particularly considered? Yet is it not notorious that the examination there is searching, extensive, embracing a great variety of subjects, and to be honourably gone through requiring a large amount of general knowledge? It is all this, and yet the certificate to which it is a prelude is not esteemed. The examination at the College of Surgeons, on the contrary, is comparatively easy; it embraces few topics, it requires little preparation to be gone through successfully, yet are the letters-testimonial which it secures of the highest importance to a young man in making his entrance on the stage of life. Wherefore this difference? Because the examiners occupy a considerable space in the public eye; because from their position as hospital surgeons and teachers they are in a condition to keep themselves constantly before the world—are necessarily and without effort kept constantly before the world; and because some of them at least have distinguished themselves in the science of their profession, and their names are as familiarly known in Paris, Berlin, Vienna, and Washington, as in London.

—No, we say, emphatically *no*; a College of General Practitioners may be numerous, may be—would be—respectable, but it can never be powerful. It would at best be another Apothecaries' Hall; a licensing shop, to which men might find it necessary to go in order to obtain the privilege of practising, but whose certificate of competency could never have any weight. And we greatly mistake our brethren if they would be content with the achievement of any *such* independence as this.

Without the privilege of licensing future general practitioners, we presume that incorporation into a separate College would not be contemplated by the present body. But we see serious difficulties in the way of their obtaining such a privilege. The College of Surgeons would certainly oppose themselves to its being granted, and we rather think that they would do so successfully. The College of Surgeons became the voluntary custodiers of the Hunterian Museum, which cost the country the sum of £20,000 to the heirs and assigns of John Hunter, and which has been kept up in its hitherto unrivalled state of preservation, at the sole expense of the College—an expense it is said little short of £5000 per annum. Did government grant the power of licensing the general practitioner to any new College or corporation, it would of course and necessarily make itself accessory to the diversion from the College of Surgeons of those funds by which that body is enabled to meet this heavy item of expense, and would have to take another burthen on its already heavily laden shoulders; and we are very much mistaken whether any ministry will ever voluntarily do any thing of the kind.

WE desire to direct our readers' attention to an able article by Dr. Scott Alison, founded on the Report for the Royal Commission of Inquiry into the Operation of the Poor-law in Scotland, and on Dr. W. P. Alison's Remarks on

that Report. We shall have occasion to return to this subject by and by. It is really one of the most important that can engage the attention of the enlightened physician and philanthropist at the present moment.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

WE have more than one urgent letter upon the dreadful state of the ventilation, and insufferable heat, of the place of meeting of this society. We remember something of the same kind last season. Fellows stay away from the meetings that they may escape not only much present discomfort, but prospective indisposition of a sufficiently distressing nature. One correspondent says, that "in a room of no very large dimensions, between one and two hundred persons were crowded, themselves sufficient to vitiate an atmosphere of twice the cubical contents in one-fourth the time during which they are there assembled, whilst eight large gas-lights are kept flaming nearly, if not quite, at the top of their power." Surely this is a state of things that might be remedied. We beg very respectfully to call the attention of the Council of the Society to the subject.

DISCOVERY OF THE NINE MISSING BOOKS OF GALEN'S PRINCIPAL ANATOMICAL WORK.

[We have the following from a learned and much esteemed correspondent. We beg to direct the particular attention of the Sydenham Society to the discovery.]

A very interesting and valuable discovery has lately been made at Oxford, which it seems right to lay before our medical brethren, though we are almost afraid that its importance will be better understood and more justly appreciated in France and Germany than in Great Britain. It is well known that Galen's principal anatomical work, called *Περὶ Ἀνατομικῶν Ἑγγεγραμμένων*, *De Administrationibus Anatomicis*, consisted originally of fifteen books, of which only eight and part of the ninth have come down to us. The contents of each book are mentioned by himself (*De Libris Propriis*, cap. 3, tom. xix. pp. 24, 25, ed. Kühn) from which account it appears that the last six treated of the eyes, tongue, œsophagus, larynx,

os hyoides, the nerves belonging to these parts, the arteries, the veins, the nerves arising from the brain, those arising from the spinal marrow, and the organs of generation: so that Galen's account of several of the most important parts of the body is contained in the lost books. In Ackermann's *Historia Literaria* prefixed to Kühn's edition of Galen (p. lxxxiv.), we find the following notice:—"E Golii Arabico codice libros xi usque ad xv editurum se promiserat Thomas Bartholinus, *De Libris Legendis*, Dissert. iii. p. 75 [p. 58, ed. 1711]. Erant Galeni *De Administr. Anatom.* libri sex postremi cum adnotationibus Jacobi Golii in Bibliotheca Narcissi, Archiepiscopi Dublinensis, n. 1787." No further information on the subject could Ackermann (who was a most diligent and accurate inquirer) obtain; nor apparently could Kühn himself, who, in the last volume of his edition of Galen, corrects some errors and supplies some omissions. In turning over the pages of a very different work, J. G. Wenrich's Dissertation "*De Auctorum Græcorum Versionibus et Commentariis Syriacis, Arabicis, Armeniacis, Persicisque*," (Lips. 1842, 8vo.) we noticed that two copies of the Arabic translation were said (p. 245) to exist in the Bodleian Library at Oxford, one consisting of fifteen books, the other only of the last six. Upon referring to Uri's Catalogue of the Oriental Manuscripts of the Bodleian (p. 135), we found that the latter manuscript was said to be in the hand-writing of Golius himself, that it had belonged at one time to Narcissus Marsh, Archbishop of Dublin, and was therefore probably the very MS. spoken of by Ackermann; and the actual examination of the two MSS. in question has shewn us that the modern one was copied from the other, the pages of the original being marked in the margin of the transcript. The original MS. is written on oriental paper, and by an oriental scribe, and contains the complete work of Galen in fifteen books. It was bought at Constantinople for forty-eight florins (rather a large price), but by whom is uncertain, nor is anything else known of its history, except that it once belonged to the Archbishop of Dublin, though it does not appear in the list of his MSS. contained in the *Catalogus Librorum*

MSS. Angliæ et Hiberniæ, printed in 1697. It appears to have been seen and used by Golius (a celebrated Arabic scholar at Leyden), who must have known that the Greek copies of the work contained only nine books, and accordingly copied the remaining six with a view to publication. He did not, however, transcribe the remainder of the ninth book, which is wanting in the Greek copies, and which is about twice as long as the portion hitherto known in Europe. The MS. was either given as a present by Golius, or bequeathed as a legacy at his death in 1667, to Thomas Bartholinus the elder, Professor of Anatomy at Copenhagen, and was in his possession in the year 1672, when he wrote his work *De Libris Legendis*. Probably after his death in 1680 it came into the hands of Narcissus Marsh, Archbishop of Dublin, and appears in the catalogue quoted above. From him it came either by gift or legacy to the Bodleian Library at Oxford, where it still remains, together with the original MS. from which it was transcribed. It should be added that (as far as we are aware,) no other copy of the Arabic translation is to be found in any European library; nor do any of the old Latin translations contain the last six books of the treatise.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Tuesday, December 3d, 1844.

DR. THEODORE GORDON, V.P. in the Chair.

Case of immense accumulation of Indurated Faeces in the Rectum, and complete suppression of the Alvine Evacuations for a month. By EDWARD HOCKEN, M.D. Physician to the Blenheim Street Infirmary, &c.

THE patient was first seen by the author in consultation with Mr. Whidborne, of Queen Square, on the 10th of June, 1844. She was then much emaciated and exhausted; the pulse 136 in the minute, and very feeble. Complaints were made of severe agony in the rectum and lower part of the belly, which latter was distended, firm, and highly intolerant of pressure. No faeces had been passed for a month, and injections, which had been frequently used, came away only slightly coloured. Food was rejected by vomiting a few minutes after it was swallowed, and even liquids rarely remained on the stomach. The vomited matters had been dark and offensive some few weeks previously, and during the course of the complaint there had been an

offensive discharge from the vagina. There were frequent efforts to go to stool from the exhibition of purgatives, which occasioned the most frightful agony, and eversion of the mucous membrane through the sphincter. On examination, the rectum was found to be completely blocked up, and enormously distended by indurated faeces, to within an inch of the anus,—bulging into, and nearly obliterating the vagina. The rectum was, however, so intolerant of the slightest touch that an opiate suppository, and a draught with hyoseyamus, were directed, to prepare the parts for further proceedings, the author intending to obtain the advice and assistance of Mr. Storks, in the interval.

History.—Three months before, the patient fell over a tray whilst nursing an infant, by which the thighs were widely and violently separated. The accident occasioned much pain, followed by menorrhagia, constipation, and the formation of indurated lumps, which were passed with much pain and difficulty. This increased till about a month ago (from June 10th), since which there has not been the slightest alvine evacuation per rectum. During her illness she had been attended by several medical men, some of whom attributed the symptoms to cancer, and others to a tumour pressing upon and obliterating the rectum. Preparations of opium had been used generally and locally, frequent enemata, and occasional purgatives.

June 11th.—The author met Messrs. Storks and Whidborne in consultation. The patient, who was almost incapable of standing, from weakness, was placed at the foot of the bed, her feet on the ground, and the trunk of the body at right angles with the thighs, lying on the bed. By means of a lithotomy scoop and the finger, Mr. Storks succeeded with some difficulty, and much pain to the patient, in breaking down and removing portion after portion of the indurated mass—some of these lumps of about three inches in diameter, which had been placed transversely in the rectum until the gut was emptied as far as could be felt. It was then washed out by a powerful stream of water from a syringe. The portions brought away were very considerable in quantity, of a most firm and unyielding description, and of a dark brown colour. It required very considerable force to remove some of these masses, so that the sphincter was slightly ruptured at its posterior part, and the patient suffered much pain from the operation.

3ss. doses of Castor Oil, with five minims of Liq. Opii Sed., were ordered every three hours, and simple enemata, with Olive Oil, every four hours.

In the evening the patient appeared much improved, and had brought off a consider-

able quantity of dark, liquid faeces, with numerous indurated lumps, apparently moulded in the cells of the colon. Abdomen very intolerant of pressure: a flannel wrung out in hot water, and then saturated with purified oil of turpentine, to be applied—and to continue as before. About forty masses of indurated faeces were passed with the motions on the following day. On the 13th and 14th the patient suffered much from severe pain and tenderness of the hypogastric region, and along the course of the rectum, for which leeches, counter-irritation, opiate enemata, and calomel and opium, were used, with a poultice to the arm. She was much better on the 15th, a large quantity of dark bilious matter having been discharged from the bowels. Acute inflammation of the vagina, with ulceration and oedema of the vulva, came on on the 16th; the uterus was low down, swollen, and tender. This condition, with more or less relief, continued till the 25th, when she went into the Middlesex Hospital. During the whole time the bowels were freely relieved, and on the 24th she had two stools of fluid flocculent matter, of a healthy colour, and unattended by pain or tenesmus.

In a note to the author, Mr. Arnott has given an account of the case up to the 22d of August. The inflammation of the vagina had continued, but from the complaints and resistance of the patient it had been found impossible to use injections, and the vagina had become partially closed by adhesions. The uterus felt enlarged and indurated from the rectum, and there was an offensive discharge from the vagina; hence Mr. Arnott inferred that malignant disease of the womb existed. The author remarked that it was curious that so many medical men had attended the patient without discovering the true nature of her complaint. He attributed this to their all having examined the patient per vaginam, and not per rectum. The value of the operation was seen in the restoration of the alvine evacuations and the relief of the symptoms; for throughout the course of the complaint there was a remarkable discrepancy between the severity of the pain complained of, and the quiet and favourable aspect of the symptoms. The impression of the author, from examinations per vaginam, was that scirrhus did not exist, but if it were present—as was Mr. Arnott's opinion—it was doubtful whether it was produced by prolonged irritation in a predisposed individual, or had existed previously to the commencement of the symptoms, and previous to the accident.

Mr. Macilwain considered that the subject of constipation was interesting to the practitioner in a point of view which had not been alluded to in the paper; viz., its

occasional simulation of other diseases, particularly of abdominal tumor. Cases in which this had occurred had frequently come under his notice. In one instance—a lady, the subject of habitual constipation—a tumor, occupying the right side of the abdomen, had existed for months, and been treated by a variety of means—among others, by leeching and blisters. The tumor was well defined, and painful and tender to the touch. Temporary relief was afforded by the means employed, but the swelling remained of the same size, and the medical attendants were quite at a loss to determine its real nature. At length he, Mr. M., was consulted, and, looking at the previous history of the case, and other circumstances, he suggested that the swelling might be dependent on a collection of feces in the abdomen. Mild aloetic doses were administered, and in the course of thirty-six hours the tumor was removed, large fecal evacuations having followed the use of the medicine.

Dr. Murphy, in some cases of obstinate constipation, had found a mechanical obstruction in the rectum, in the form of bands passing across the bowel just above the sphincter. Such a cause did not exist in Dr. Hocken's case.

Observations on the Relaxed Rectum. By
H. HUNT, M.D.

The author describes this as a malady of not unfrequent occurrence, and productive of much inconvenience and distress. The most prominent symptoms are obstinate constipation, a frequent desire to evacuate the bowels, a constant sensation of load in the rectum, which is not relieved by an evacuation, and the discharge, after much forcing, of mucus streaked with blood. The bladder, urethra, and other adjacent organs, often participate in the irritation.

On examination, the rectum will be found preternaturally enlarged, and more or less filled with large folds of mucous membrane pressing down on the anus, which impede the evacuation of the feces, introduction of instruments, and injection of enemata.

This morbid condition of the mucous membrane the author attributes to a neglected state of bowels, and repeated and great distension of the rectum by feces, which causes the mucous membrane, when the bowel is empty, to hang in loose folds.

This disease, if neglected or mismanaged, gives rise to prolapsus ani, an irritable and painful state of the sphincter, and an intromission of the upper and undilated portion of the intestine into the lower and dilated part.

The treatment recommended for the simple relaxed rectum is the avoidance of all aperient medicines, and the injection of

a pint of cold water into the bowel every night previous to going to bed; the removal of the prolapsus, and the application of belladonna ointment to the irritable sphincter.

In the case of intromission of the rectum, in addition to the use of the cold-water injection, the exhibition of some mild aperient, taking care that whilst a costive or hardened state of the feces is prevented, purging is avoided; and a course of the Hyd. c. Cretâ with hyoscyamus or conium, or of the iodide and sarsaparilla.

Dr. J. Johnson considered that the first class of cases described in the paper were common enough. The author, in these cases, seemed to deprecate altogether the use of aperient medicine; in this respect he, Dr. J., differed from him. It must be recollected that to effect a cure the colon as well as the rectum must be acted upon, as feces often accumulated above the latter organ. Now the colon would not be reached by the small cold-water injection recommended in the paper, and these injections were far from being always harmless, for they were occasionally productive of great pain and severe tormina. He had even seen them producing faintness in a patient from these causes. In the treatment, then, of these affections, he preferred the milder aperients, such as tartrate of potash, or confection of senna, for these produced no irritation or straining; but were of the most essential service. In cases of relaxed and protruding rectum, he had used Ward's paste with much advantage. Under its employment the folds of the rectum became corrugated, and the canal altogether strengthened. With respect to local mechanical contrivance to keep the weakened bowel in position, he knew of none which in efficacy could be at all compared to two silk handkerchiefs, one of which was placed round the waist, and the other, attached to this behind and in front, kept a soft piece of sponge covered with linen in such a position that it pressed gently on the lower part of the rectum, and kept it in position.

Mr. Bransby Cooper bore testimony to the value of mild aperients in the cases mentioned by Dr. Johnson. In the treatment of prolapsed rectum, however, neither aperients nor mechanical contrivances of any kind were of half the service as the adoption of the plan recommended by Dr. Hunt in his paper—the evacuation of the bowels at night. When this plan was adopted the patient had the advantage of remaining in bed for seven or eight hours, during which time the rectum would be kept in position, and by this means a perfect cure might be effected; a termination rarely to be expected from the use of medicines or of

mechanical support. The rule alluded to was one of great value in all diseases of the rectum. When the bowels were evacuated in the morning, irritation was kept up during the day, either by the sitting posture or by moving about, and all attempts at cure were frustrated.

Mr. Henry Lee stated that it appeared to him that the disease under consideration had hitherto been very imperfectly explained. In dissecting the rectum, a strong band of muscular fibres is found, arising from the posterior part of the pelvis, taking a course downwards and backwards, and encircling the lower extremity of the bowel. These muscular fibres are part of the levator ani, and although not usually described, are very important with regard to the disease in question. They lie in close contact with the sides and posterior part of the bowel, the lower two inches of which are thus encircled by strong muscular fibres, taking the same direction, and performing the same office, as the fibres of the sphincters ani. Whenever it happens that a portion of the relaxed mucous membrane comes within the grasp of these muscular fibres, the very natural effect is, that the return of the blood in the veins in the constricted part is retarded; and this in reality is the cause of the deep-seated dull pain, the tenderness, and the inflammation, which are so frequently observed in these cases. The principal object of local treatment in such instances is to relieve the inflamed portion of mucous membrane from the constriction caused by the muscular fibres, which has just been described. Temporary relief is immediately produced by returning the relaxed and congested mucous membrane to its natural station; but the benefit thus derived continues as long only as it is retained there.

It has been stated that the different instruments which have at various times been used in this complaint, instead of giving relief, have tended to increase the irritation of the part. This appears in a great measure, if not altogether, to depend upon the mode in which these instruments are constructed. They are generally so contrived that the bulb (by means of which the instrument is retained in the bowel) is placed, when the instrument is worn, immediately within the grasp of the muscular fibres of the levator ani, and it is to this cause that the irritation complained of is principally to be attributed. If, however, the stem of the instrument is made sufficiently long, so that the bulb, when introduced, is situated above instead of within the circular fibres of the levator ani, the instrument can be worn not only without inconvenience but often with the greatest comfort. Such instruments are kept by Messrs. Savigny, in St. James's

Street. With regard to the plan proposed of removing portions of the mucous membrane in this disease, Mr. Lee considered the application of the strong nitric acid to the part as a safer and much less painful operation than that which was usually performed by means of a ligature.

Dr. Dickson supported the opinion of Dr. Johnson in regard to the employment of mild medicines, which acted on the bowel above the rectum, in case of obstinate constipation. He had found no remedy more efficacious in these cases than a combination of extract of hyoscyamus, and blue pill, in large doses. This was often of service in cases even of stricture situated high up in the bowel. He mentioned also with commendation a medicine for the knowledge of which he had been indebted to the late Dr. Gooch; it consisted of a mixture of aloes with sulphuric acid. In one instance in particular he had employed this medicine with the utmost advantage. The patient was a lady of constipated habit, who on one occasion had no movement of the bowels for sixteen days. Various gentler means to obtain an evacuation having been employed without effect, the aloes and sulphuric acid were administered; the bowels were quickly relieved, and during the remainder of her life, a period of six years, they were always easily acted upon. She died from diseases altogether independent of constipation. With respect to mechanical support in prolapsed rectum, he spoke with strong approbation of an instrument made by Mr. Lavvdy. The bowel by this apparatus was supported without inconvenience to the patient, and a cure by its means was occasionally completely effected.

Dr. Leonard Stewart related a case in which protrusion of the rectum had existed constantly for eight years, and occasioned much suffering. The patient was seized with apoplexy, for which bleeding and mercury were resorted to. The functions of the bowel were completely restored under the influence of the salivation.

Mr. Macilwain considered that all the speakers, as well as the author, had taken too confined a view of causation in the diseases under discussion. The cause was more frequently in the portal circulation than in the rectum, and remedies applied to that part of the system would be found efficacious. This principle had been acknowledged, though not distinctly mentioned, in the recommendation of remedies whose chief action was on the liver. He spoke of the necessity of caution with respect to purgatives, which he had seen produce mischief in these affections.

At the next meeting papers will be read by William Ferguson, Esq. and Dr. Alison.

PHYSICAL SOCIETY OF GUY'S HOSPITAL.

November 30, 1844.

DR. LEVER in the Chair.

At a very full meeting of this society, Mr. Oldfield, with the sanction of Mr. Key, brought forward the particulars of a case of aneurism of the right subclavian artery, occurring in a young woman, and upon whom an operation had been commenced by Mr. Key, for the purpose of either passing a ligature around the arteria innominata, or of tying both the subclavian and the carotid, near their common origin, as the state of the parts when disclosed by the knife might render most advisable.

Mr. Key was induced to attempt this operation as a last resource for the well-doing of the patient, because no clear indications of aneurismal disease of the arteria innominata or arch of the aorta were discoverable, —an opinion in which the stethoscopic authorities of the hospital coincided, except Dr. Hughes, who pronounced the arteria innominata implicated. After completing the steps of the operation required for reaching the arteria innominata, Mr. Key found it impossible to surround that vessel with a ligature, in consequence of a tumor connected with it; and the attempt was finally abandoned. The operation lasted one hour; and the wound went on so favourably, that it had become nearly filled with granulations at the time of the patient's death, which took place the 23d day after, when she sank with symptoms of pulmonary distress and exhaustion. Mr. Oldfield read a minute account of the symptoms, steps of the operation, and after-treatment; and also exhibited the diseased parts to the society. The tumor, which prevented the completion of the operation as originally intended, was found to consist of an aneurismal enlargement of the upper part of the arteria innominata and origin of the subclavian artery, the carotid artery being comparatively healthy. This enlargement, together with a mass of diseased glands, had pressed on the right bronchus, into which it would probably have opened, had life been prolonged; it had, by its pressure, been the immediate occasion of the fatal termination.

The paper concluded with some judicious remarks on the difficulty of diagnosis in this peculiar and very interesting case, and on the superior applicability of the distal operation in cases of aneurism of the innominata in general, which Mr. Oldfield contended was proved by the recorded cases of success elsewhere, although the distal operation for aneurism had not as yet been regarded in a favourable light at Guy's Hospital.

An animated discussion ensued, in which Drs. Brereton, Chevers, Munk, and Hughes, and Messrs. Callaway, Jun., Lloyd, and France, took part. The stethoscopic diagnosis of internal aneurism, both thoracic and abdominal, with the nature and source of the systolic and diastolic bruits which accompany them, formed the staple of debate, but the propriety of declining operation altogether, and trusting to spontaneous cure by very small and oft-repeated bleedings, was also canvassed. A case of thoracic aneurism in St. Bartholomew's Hospital, where Mr. Paget, with the sanction of Dr. Latham, had employed venesection fifty times, was related by Dr. Brereton to have proved completely successful, as demonstrated when the patient died of concomitant disease of the lung two years after.

The usual thanks were voted to the author, and a communication on the subject of a peculiar disease of the intestine, from Mr. Hiff, announced by the Secretary for the next meeting.

THE ORTHOPÆDIC INSTITUTION.

To the Editor of the Medical Gazette.

SIR,

In last Saturday's *Lancet* appears a letter, signed "A Constant Reader," assuming the Editor to be "of course aware" that in consequence of the "bad management" of the above Charity the following resignations had taken place:—The Right Hon. the Earl of Eldon, the President; the Earl of Arundel and Surrey; Dr. Stromeyer; Amos Swaisland; Frederick Heisch, and Frederick Heisch, Jun. Esqs.—Vice Presidents, and suggesting that it is best known to the Committee why "this fact is kept a secret." The Committee will greatly esteem your kindness if you will insert in your next publication my official contradiction of that statement.

The Earl of Arundel and Surrey, Dr. Stromeyer, and Mr. Amos Swaisland, have not resigned, nor is the latter a Vice President; and though the Earl of Eldon and Messrs. Heisch have, it was not alleged to be on account of bad management by the Committee, nor was it so; but by reason of circumstances not originating with the Committee, and in respect of which they had only a limited power. The retirements which have taken place, and every occurrence connected therewith, and with the general affairs of the Charity, have been laid by the Committee (who never intended to keep them secret) before a full Court of Governors, at which Philip Hanbury, Esq. V.P. presided, and a resolution of approbation and confidence was unanimously voted to the Committee.

I will not occupy your valuable columns further than by expressing a sincere belief that the injury which it must be the object of "A Constant Reader," by his anonymous misstatements to do this very useful Institution, will be averted.

I have the honour to be, sir,

Your obedient servant.

H. GILLET GRIDLEY,

Hon. Sec.

Bloomsbury Square,
Nov. 22, 1844.

MR. TAYLOR ON DR. GUY AND HIS REVIEWER.

To the Editor of the Medical Gazette.

SIR,

As I am in some measure interested in the question at issue between Dr. Guy and the reviewer of his "Principles" in your journal, I beg the insertion of the following remarks.

Your reviewer accuses Dr. Guy of having made a very unfair use of my "Manual of Medical Jurisprudence and Toxicology," not merely in adopting, with some unimportant variations, the plan pursued by me in treating the subject of poisons, but in appropriating, in an abridged form, a large portion of the work. The substance of Dr. Guy's answer to this charge appears to me to be, that he has made no more use of the "Manual" in the composition of his work than any author is entitled to make of the works of others. The analogous views of Dr. Christison and myself on the effect of "habit" on poisons—a point on which no toxicologists of the least experience can possibly differ; and the difference of opinion to which Dr. Guy refers as existing between himself and me "on the mode of operation of poisons"—a subject on which no two writers have ever yet agreed—are quite beside the question. The charge of your reviewer, as I understand it, is one of general plagiarism; to which Dr. Guy pleads "not guilty."

If, as the author whose work is alleged to have been pirated, I may be allowed to express an opinion on the subject, I must declare, with regret, that I consider the statement of your reviewer to be correct, and that, in my opinion, the "Manual of Medical Jurisprudence" has been much more frequently used by Dr. Guy, without reference or acknowledgment, than is either proper or becoming in one writer following another so closely on the same subject. I may be wrong in this opinion, and may have been, perhaps, the more readily induced to adopt it, from the fact of Dr. Guy having already appropriated, in the second part of his "Principles," a large portion of the

"Elements of Medical Jurisprudence," published by me in 1836, and now suppressed. In the *Lancet* for October 19, Dr. Guy has voluntarily made a public apology for the error he then committed; but in reference to the "Manual" he wholly denies the charge; although, so far as I am concerned, I consider myself to be more injured by the manner in which he has treated the "Manual" than by the way in which he dealt with the "Elements."

With respect to this denial, I shall only observe, that Dr. Guy allowed a year to elapse before he discovered, or at least announced, that the plagiarisms from the "Elements" had become "a subject of more than private remark;" and perhaps, after another year, notwithstanding the plea of "not guilty" with which he now "boldly" meets the charge, he may make the same discovery with respect to the use which he has made of the chemical toxicology contained in the "Manual." All that I have to say in the matter is, that if, on a comparison of the two works, the profession, especially those members of it who are acquainted with medico-legal literature, and who have no difficulty in deciding on what belongs to one man and what to another, as readily acquit Dr. Guy of the charge brought against him by your reviewer as he acquits himself, I shall be perfectly satisfied; but until then I cannot avoid entertaining the conviction that his chemical toxicology is substantially abridged from that lately published in my "Manual," with occasional interpolations from Christison and Beck. If Dr. Guy demur to this opinion, and if he believe that an author is incapable of identifying his own property, although its shape and form be in some respects altered, and intermixed with quotations from other works, let the decision rest with the profession. He has put in his plea of "not guilty," and the verdict, according to all the rules of justice, must rest with others, and not with himself.—I am, sir,

Your obedient servant,

ALFRED S. TAYLOR.

Cambridge Place, Regent's Park,
December 3, 1844.

CASE OF MISS MARTINEAU.

To the Editor of the Medical Gazette.

SIR,

IN the notice of Miss Martineau's case, which appeared in the *Medical Gazette* of last week, it is assumed that an erroneous judgment has been formed as to the nature of her complaint, and that her age is different from what it really is.

As the medical adviser of Miss Martineau

during the last five years, I have to request that you and other members of the profession may suspend your judgment till a future period, when I shall probably be able to prove that neither in diagnosis or prognosis (as to the final issue) of her complaint, have I been incorrect.

Of the rationale of her recovery, I forbear at present to speak further.—I remain, sir,

Your obedient servant,

T. M. GREENHOW.

Newcastle, Dec. 4th, 1844.

[We had some further observations on the case, which we of course suspend for the present.—ED. GAZ.]

DR. ABERCROMBIE.

Our profession has lost another of its ornaments. John Abercrombie died suddenly at his house, on the 14th of November, in the sixty-third of his age. Dr. Abercrombie had been in his usual health; he had breakfasted; several patients were waiting, and the carriage was at the door. His servant thinking his master stayed longer than usual, opened the door of the study, and beheld him stretched on the floor on his face, with his arms extended, and quite lifeless. On opening the body, the cause of death was found to have been a partial rupture of the left ventricle of the heart, implicating one of the coronary arteries, and the corresponding vein. The pericardium was full of blood. The rent in the ventricle was about an inch and a half in length, and was situated midway between the base and apex of the heart; it did not extend into the ventricle of the heart itself. The substance of the organ was soft, and loaded with fat. The vessels were ætheromatous.

No man ever lived more respected by a large circle than Dr. Abercrombie. His professional brethren followed him to the grave, and in such numbers that the procession had all the characters of a public funeral. The free church presbytery, and the Colleges of Physicians and Surgeons, walked four deep. "The ceremonial was unostentatious and profoundly solemn."—For other information vide *Cormack's Journal*, Dec.

TO CORRESPONDENTS.

WE must decline inserting anything more on the case of Belany. The medical world has formed its opinion of that case; some learned members of the legal profession have also stated in their Journals what they think of the verdict he obtained, and the public, more especially those of his own neighbourhood, who were best able to judge of his character, have given unequivocal

proofs of what they think of him. Dr. Glover, and Belany's other friends, will do well to let that person's memory fall into the shade.

The Editor of the *MEDICAL GAZETTE* must positively decline becoming umpire betwixt one gentleman and another on any point in dispute between them.

MORTALITY OF THE METROPOLIS.

Deaths from all causes registered in the week ending Saturday, Nov. 23.

ALL CAUSES 914

Medicine and the Collateral Sciences.

FRIDAY, DECEMBER 13, 1844.

REPORTS, OF CASES TREATED IN UNIVERSITY COLLEGE HOSPITAL.

By H. FEARNSIDE, M.B.,

[Continued from p. 184.]

Hysteria and "spinal irritation."—Extreme sensibility of the surface of the upper part of the body; much headache, giddiness, &c. Failure of depleting remedies in relieving these symptoms—improvement under the use of tonics.

CAROLINE WHITE, æt. 18, admitted into University College Hospital, under Dr. A. T. Thomson, June 13th, 1843. She is a strong young woman, of sanguine temperament, and florid complexion. She is a native of, and has always resided in London, and generally in open and healthy parts of the town. She has always had an ample supply of the necessaries of life. Her parents are living; her father is strong and healthy, but suffered from rheumatism when young; her mother has always been delicate, and has been the subject of asthma since the age of eight years. The patient has been in service about three years; previously, for an equal length of time, she was occupied as a silver burnisher,—an employment which she relinquished from its involving much confinement. About fifteen months ago she injured her left side, and the back of her neck, by falling down some stairs, and she has since suffered from pain in the side on active exertion, or coughing: before this time she is not aware that she ever had any more serious ailment than a cold.

During a considerable part of the last nine months she has resided in Northumberland Street, and near the water side; she describes the house and situation as being very damp, and states that at particular tides the water penetrates through the ground, so as com-

pletely to inundate the cellars. For the same period her work has been more laborious than she had previously been accustomed to; she had been in the habit of staying up late at night, and rarely or ever went out, except for a short time upon Sunday. After being about a month in this situation, her health began to fail; she lost her strength, suffered from pains in her limbs, and frequent headache and giddiness. These symptoms gradually increased, the symptoms became more localised, and after their persistence for about two months she had a severe attack of rheumatism, which confined her to her bed for five weeks. She resumed her employment before she was completely well again, and in about a month, from some exposure, took cold, and lost her voice for some time. Her health appears never to have been completely re-established after the rheumatic attack; she frequently experienced pains in the limbs,—did not regain her strength and flesh, and had repeatedly slight hysterical paroxysms.

On June 2nd, having previously suffered for some time from a severe cough, she was suddenly seized with difficulty of breathing, which continued for about a quarter of an hour; on this ceasing, she had rigors, succeeded by much heat of skin, and headache, and subsequently by syncope; she had also pains in the limbs, especially in the vicinity of the joints. On the following day the symptoms increased in severity, and the headache was intense; a venesection performed on the ensuing day afforded much relief: since this period she states that every afternoon she has had an attack of rigors of about half an hour's duration, followed by heat of skin, &c.; on further inquiry, however, it appears that these alternations recurred at other times during the day. The headache and pain in the limbs subsequently became very distressing, and have continued so to the present time: a week ago, she had a violent hysterical fit, during which, ac-

cording to her own statement, she was insensible for about three hours.

State upon admission.—The hands and feet are rather cold, but the head and rest of the body are rather above the natural temperature; the face is flushed; there is no swelling or redness about any of the joints, but she complains of much pain in the shoulders and knees. There is excessive sensibility to pressure over the spinous process of the vertebræ as low as the lumbar region: pressure over the dorsal vertebræ causes great and distressing dyspnoea, and a lancinating pain in both arms, but especially in the left one. There is extreme tenderness of the whole scalp, and pressure upon this part, or upon the spinous processes of the upper cervical vertebræ, causes dimness of vision, a sensation and stiffness of weight about the eyeballs, and faintness and heaviness of the head. She has almost constantly giddiness, and severe headache: she frequently has tinnitis aurium, and the sensation of sparks passing before the eyes.

There is great superficial tenderness below the left mamma, (the situation of the part injured by the fall before referred to,) and this exaggerated sensibility exists in a greater or less degree over the whole front of the chest, and over both arms, especially their upper parts, and around the shoulder-joints. She has some cough, and complains of its occasioning pain in the left side; there appears to be slight dulness on percussion over the upper part of the left side of the chest, but the respiratory murmur is generally healthy; number of respirations 26 per minute. The sounds and impulse of the heart are healthy; pulse 96, compressible. The tongue is dry, and covered with a yellow fur in the centre; she is very thirsty, complains of some soreness of throat, and nausea—has no appetite; bowels open; the liver descends about two fingers' breadth below the margin of the ribs; no enlargement of the spleen; urine scanty, high-coloured, and turbid, from the deposition of the lithates. The catamenia were present about a fortnight ago; they appeared first at the age of fourteen years; two years afterwards they were absent for about nine months, but since that time they have appeared with tolerable regularity; sometimes, however, recurring after intervals of three weeks only, or even less. Menstruation is usually painful, and the flow scanty.

Treatment, and subsequent progress of the case.—Under the impression created by the statements of the patient that the most prominent symptoms were of a periodical character, quinine was prescribed, and with this was associated a combination of calomel and colchicum, for the purpose of removing

the relics of the rheumatic attack. After the lapse of a day or two, the true nature of the case being more apparent, these remedies were discontinued, and sixteen ounces of blood were taken from behind the ears by cupping; purgatives were also prescribed. These depleting measures at first appeared highly beneficial; the giddiness, headache, and indistinctness of vision, were diminished; the surface of the upper part of the body no longer manifested that extreme sensibility which had been observed on the patient's admission, and pressure upon the spines of the dorsal vertebræ ceased to occasion in the same marked degree those peculiar effects which have been mentioned in the history of the case. The improvement, however, was but temporary; the headache and the symptoms mentioned returned, and were again relieved by the copious abstraction of blood. The expiration of a few days witnessed their re-establishment in all their original severity; for the third time free cupping almost completely removed them, but, as on former occasions, this promise of the restoration of health proved delusive, and it was judged expedient again to have recourse to the same remedy; a blister was applied to the nape of the neck, and a cold lotion to the forehead; purgatives also were freely administered. But these means afforded only partial relief, and on July 1st, whilst under their full influence, the patient was suddenly seized with throbbing of the temporal arteries, lancinating pain in the eyes and ears, and much headache; these symptoms were succeeded by total loss of vision for about four hours, and a considerably longer period elapsed before she could see with any distinctness; the headache continued, but was relieved by the recumbent posture; her sleep was broken, and disturbed by frightful dreams; the pulse was 80, soft, and rather jerking;—the tongue slightly furred. An entirely opposite plan of treatment was now adopted; the carbonate of iron in the nascent form was prescribed in combination with myrrh, and a pill containing assafoetida and henbane was directed to be taken every night. The good effects of the change were soon apparent in the diminution of the headache, and the increased brightness of the eyes, and the vivacity of the countenance; but on July 4th, or three days after the commencement of this altered plan of treatment, the patient left the hospital.

Remarks.—As mentioned above, the statements of the patient upon her admission into the hospital gave rise to the impression that there was something of a periodic character in the affection under which she was suffering. She asserted that for some time she had had an attack of rigors daily at three o'clock, P.M.; so that although the

period of the accession was not exactly that seen in tertian ague, still it was sufficiently near it, to lead upon a first view to the supposition that the case was one of double tertian.

Upon more minute investigation, however, it appeared that the attacks of rigors were not confined to the time mentioned; and, also, that although succeeded by reaction, still there was not generally such increase in the perspiration;—thus altering the aspect of the case completely.

Upon her admission the patient was suffering under the remains of a slight attack of rheumatism, there being some pain about the shoulders, knees, and hips; this, however, soon disappeared. The more prominent symptoms were clearly those of hysteria, and aggravated spinal irritation. The appearance of the patient, the distinct hysterical fit which she had a few days previously, and her history, from which it appeared that she had suffered from the affection repeatedly before, were sufficient to point this out as her true complaint. But there was also spinal tenderness, (to use a conventional expression,) of unusual extent and development; the pathological condition of which this is the index affecting the greater part of the spinal cord. As connected with this state, we may enumerate the excessive tenderness of the scalp, and the headache, giddiness, indistinctness of vision, sense of weight, and heaviness over the eyes, occasioned by pressure over the cervical portion of the spine. The excessive sensibility of the surface of the chest, arms, &c., and the dyspnoea occasioned by pressure upon the dorsal spines, would appear to stand in the same relation to the nervous centre in that portion of the vertebral column. But the cerebrum itself was also implicated, as was manifested by the headache, giddiness, tinnitus aurium, disordered vision, and disturbed sleep, of which the patient complained at the time of her admission, or subsequently.

The true nature of this affection would seem to consist in irregular distribution of blood through the nervous centres generally, and spinal cord in particular. This view is supported by a consideration of the circumstances under which it is most usually developed, as well as by the effects of treatment. In young females it is usually seen in connection with irregular or scanty menstruation—the influence of which periodical discharge upon the circulation is well known. But in addition, there appears to be required a peculiar condition of the nervous structures themselves, either congenital, or the result of a peculiar mode of life,—causes long operating, and tending to deteriorate the general health, and induce excessive nervous sensibility;—hence, from the greater

mobility of the nervous system in females, most of the cases of this affection occur in this sex. The same state would appear to be more rapidly produced by a blow or fall, especially upon the back.

In subjects who possess this faulty organization, whether congenital or acquired, a peculiar state of the nervous centres is readily induced, characterised in particular by undue development of the functions of the nerves, arising from the posterior division of the spinal cord;—hence the great sensibility of the parts to which these nervous fibrils are distributed, and hence the tenderness upon pressure over the spine, from the cutaneous branches of the posterior division of these nerves ramifying in the integuments near the vertebral column. In some instances, the anterior portion of the spinal cord, and the motor properties of the nerves thence arising, are affected, as was seen in this case, in some degree; pressure over the upper dorsal spines occasioning (by reflected irritation) severe paroxysms of dyspnoea.

The causes of the rheumatism in this case appear to have been continued exposure to damps, cold, &c.; and as we have had occasion to observe in other instances, the disease was rather due to agencies which had long been in operation, than to any single exposure.

As regards the spinal irritation, it appears probable that the fall upon the back which the patient had sustained, was one link in the chain of causation. But, as before remarked, it is in particular states of the system that the influence of such accidents is most perceptible. A similar observation will apply to the development of hysteria. In the present case, these affections supervened only after the patient had undergone the debilitating treatment required for subduing a tedious and painful disease, after long-continued confinement in-doors, and late hours; all,—causes highly conducive to the production of that state of the nervous system before adverted to, and which appears to be the essential element in their nature. As is generally observed in examples of these affections, they were associated with a disordered state of the menstrual function; small as is the actual amount of fluid thrown off by this channel, its due elimination has much influence in maintaining a healthy state of the female habit.

The effects of the treatment adopted in this case may give rise to one or two useful observations. The patient was a robust-looking young woman, with a very florid complexion, and her appearance and complaints not unnaturally led to the adoption of free depleting measures. With what success, the history of the case has sufficiently disclosed; the relief afforded by

the abstraction of blood, although considerable for the time, was of short duration, and became shorter after each successive cupping. Notwithstanding her apparent plethora, it must be remembered that for a considerable time her health had been below *par*,—also that she had undergone venesection, and other depleting treatment, before her admission into the hospital. Hence the importance of judging of the state of a patient, not by some absolute and arbitrary standard, but by a reference to his or her habitual condition. The antiphlogistic regimen, in this case, perpetuated the evils which it was intended to remove. As from the absence of the influence of atmospheric pressure, the contents of the cranium remain a fixed quantity, after large depletion the circulation is no longer in harmony with that of the system at large; nay more, from the feeble action of the heart in such cases the blood would seem to accumulate, and possibly even stagnate, in the venous sinuses. Now, although cupping may act as a powerful local derivant for the time, yet as the vessels are rapidly distended again, the continuance of the affection is rather favoured than otherwise. Such were the views which led on July 1st to an entire change of treatment, and even in the short time during which it was tried unequivocal benefit resulted from it. A continuance of the treatment then enjoined, with liberal diet, including an allowance of malt liquor, and out-door exercise, would probably soon restore the patient to her wonted health.

ON FRACTURES OF THE FEMUR.

By W. LYON, Esq.

Lecturer on Surgery, and lately one of the Surgeons of the Glasgow Royal Infirmary.

(For the *Medical Gazette*.)

As stated by me in my paper "On the Statistics of Fractures,"* I treated in all forty-one cases of fractures of the femur, thirty-five of which were in the male, and only the comparatively small number of six in the female. I tried several modes of treatment, and as the number of cases was, I think, sufficient for enabling me to judge of the merits of the plans employed, I shall detail a few of the more interesting examples, and give the inferences supplied by my opportunities for observation. With few exceptions, where the semi-flexed method was demanded by peculiar circumstances, in all the cases the

patients were treated with the limb in the straight position. Into the theoretical reasons for the preference given by some to the extended, and by others to the flexed method, it is not my intention to enter: in public and private I have in different cases frequently used both plans, and do not doubt but that, by careful management, good cures may be accomplished by either of them, a good deal depending upon the skill and care of the surgeon, as well as the particular position or apparatus employed. For the case of the patient, (for obtaining a cure without deformity, or shortening,) the observation of the treatment in the straight position entitles me to assert, that if any method can answer as well, none is superior; and that for facility of application, and ease in after management, as far as both patient and surgeon are concerned, no plan has stronger recommendations. There are, however, important differences in the modes of carrying out the principles on which the plan by extension is based, and it is to these I have more especially to direct attention.

When I entered on my duty at the hospital, I adhered to the mode of treatment previously in use, which consisted in the application of a few turns of a common roller over the foot and ankle, a Scultetus over the leg and thigh, a splint cloth, long enough to extend from hip to foot, three bran pillows, one for the outside from middle of trunk to leg and foot, one for inside, from perineum to beyond sole, and the third in front, from groin to knee, and corresponding to these three thin wooden splints. While the limb was kept extended, and coaptation effected, the bandages were applied, and the splints, folded in the margins of the splint cloth, were laid along the limb, and kept firmly in their places by three or four straps buckled at different points; and the external one was in addition bound firmly to the trunk or pelvis.

In this manner the limb and trunk were retained in a straight line, and the prominences and depressions on the limb, moulding for themselves corresponding pits and eminences on the bran pillows, and these again firmly pressed on all sides by the splints, acted on by the straps and buckles, an accurately fitting soft case was formed,

* London and Edinburgh Journal, Jan. 1844.

and displacement of the fragments prevented.

About one-third of our patients were treated in this manner, and were discharged without perceptible deformity. But to be effective, the apparatus required to be kept very firmly applied: however well put on, the bandages and straps soon become loose, necessitating frequent adjustment; while on the other hand, if tight, they occasioned much restlessness, and not unfrequently pain was complained of over the more prominent parts, especially the inner condyle of the femur, and in two instances such consequences occurred as caused the discontinuance of this method of treatment.

W. A., aged 12 years, June 19th, 1841. To-day he suffered an oblique fracture of femur: there is shortening to extent of one and a half inch, and toes are much everted. The fracture was put up by method above described, and union had taken place, but not firmly, when he complained of pain over inside of knee, which persisting for a day or two, the apparatus was removed, when there was found, over internal part of articulation, an unhealthy looking sore, about the size of a shilling. Retentive measures were omitted, emollients applied, but these were enlarged, and became deeper. The pain increased, and was attended by redness and swelling, and from the glairy nature of the discharge*, and the use of the probe, it became evident the ulceration had extended, and opened the articulation. High constitutional disturbance took place, soon followed by hectic and diarrhœa: these were not checked by a variety of treatment employed: he was daily becoming worse: the danger appeared imminent, and after repeated consultations at intervals of several days, assent was at last given to remove the limb, which was done by lateral flap method, in the lower third of the thigh. He now rapidly improved, and was soon discharged.

Every kind of treatment I could think of was tried to obviate the effects of the opening into the articulation, and amputation was delayed as long as was consistent with safety; indeed, fully longer; the debility, hectic, and diarrhœa which were present, shewing the powerful influence of the local dis-

ease, which in these circumstances often induces such secondary affections as oblige us to postpone, altogether prevent, or persist after the performance of the operation, and destroy the patient. So far as my observation in private and hospital practice has extended, it is rare indeed, but particularly in the vitiated air of an hospital, to see a patient escape without loss of limb, who has had a *large previously healthy articulation suddenly and extensively* opened in any manner, but more particularly by ulceration, where immediate union of the wound is next to impossible: in these cases, the patients have generally either lost their limbs or their lives, and sometimes both: and it ought to be recollected, that in such conditions the attempt to save the limb is one of great danger, and the question is not, whether some have been saved without amputation, for of that there is no doubt, but whether out of a given number, if all were subjected to primary amputation, a larger proportion would not recover than by pertinacious attempts to save the seemingly favourable cases. From this manner of procedure, some limbs would be unnecessarily sacrificed, but lives would be saved otherwise lost in the attempt to preserve members, and while I do not urge the indiscriminate performance of amputation in all cases of this kind, I feel pretty confident of the correctness of the opinion above given; viz., that a greater number of lives would be preserved, by immediate amputation, say in a given number of instances, where the knee, shoulder, or limb, has been freely opened, than by what is quaintly, but unjustly, called conservative surgery. For it is a great, and often fatal mistake, to suppose that in an instance of the assumed kind, we may *safely* try to save, and if unfavourable symptoms shew themselves, we can retrace our steps, and operate. During the trial, such complications as phlebitis, ulceration of intestinal mucous membrane, pneumonia, pleuritis, or the like, very often arise,) the cause still existing) defy all treatment, prevent us from operating, or kill the patient after the operation has been performed. These points deserve consideration in balancing the risks before we determine the procedure we intend to follow in these dangerous circum-

* I am perfectly aware of the impropriety of trusting much to this sign.

stances: the age of the patient, his constitution, the locality in which he is to be treated, the size of the injured articulation, the kind and degree of the lesion it has suffered, ought all to form elements in our decision. Youth is more favourable than adult or advanced age: intemperance unfits for bearing up against such injuries: recovery is much more probable in private than hospital practice: the danger increases proportionately as the size of the articulation augments; and according to the extent, and simple or complicated nature of the wound. All these must be weighed, and in addition the risks from the operation required, which, if primary amputation in the thigh in an adult or aged subject, is an injury not much less mortal, we fear, than the opened knee, the effects of which it is intended to avert.

This was a very serious termination to a simple fracture of the femur, and that in a young subject too. It may be urged, that the issue here was not justly referrible to the mode of extension employed, but arose from the improper or unduly firm application of the apparatus, and that the boy previous to the formation of the ulcer must have complained of much uneasiness, attention to which would have prevented a serious result. I believe greater firmness of the apparatus was not employed than was absolutely requisite for keeping the *very obliquely* fractured fragments adjusted: our patient was of such fretful disposition as effectually guarded him against our neglect, and I detail the case principally with a view to shew that, *without much pain*, the constant equable pressure over the soft tissues covering the prominent internal condyle, may, by directly destroying their vitality, or indirectly, by inducing inflammation and ulceration, occasion the dangerous lesion of an opened knee-joint: and that therefore, if the plan of treatment described is to be followed, the knee should be frequently and carefully examined; a practice, however, both inconvenient and injurious.

Soon after this occurrence, a patient under treatment for a similar injury complained of continued slight uneasiness over the knee, and that not being abated by making a depression in the bran pillow with the finger, at the uneasy part, a procedure often requisite

in this method, the apparatus was removed. The parts over the internal condyle were found red and tender, the whole articulation seemed slightly inflamed, and the excitement did not subside until leeches and cold lotion had been repeatedly employed. Had we not been warned by the serious result in our former case, there is no saying how far the injury might have proceeded here, as the uneasiness was not so considerable as otherwise to have attracted attention.

These occurrences, the fretfulness of the patients, from pressure at some point or other, the necessity for frequent adjustment, and of almost daily comparison of the length of the two limbs, lest shortening existed, finally prevailed on me to give a trial to the method of Desault.

It has been theoretically objected to this plan, that by its use the normal curvature of the femur is destroyed, and that the state of extension in which the muscles are kept excites them to constant and violent action. Of the first objection, I have, in the thirty patients treated by this method, seen no proofs: the length, the activity, power, and countour of the member, being in all the patients unimpaired.

As to the contraction excited by the extension, if it exists at all, it is very soon overcome; the muscles, relieved from the pricking by the extremities of the fragments, soon become passive, and a slight degree of force is sufficient to resist their action.

The correctness of the principles on which this method is based was established to our satisfaction by the success which followed its employment, and this was corroborated by the exemption, with a single trivial exception, from the least injury, of any of the patients treated by it, and also by the comfort they obtained after and while it was applied. They almost universally expressed themselves as feeling perfectly easy: indeed, I cannot conceive it possible for persons with such kind of injuries to suffer less than our patients did. But correct as the principles of the treatment are, I doubt not that the ease the patients experienced, their cure without deformity, and another great recommendation of this method, both for the surgeon and patient, the avoidance of any necessity

for interference or adjustment worth mentioning after the first application, were attributable in a great degree to the attention, skill, and dexterity of Dr. William Findlay, who acted as my clerk for the eighteen months during which I used Desault's plan. The putting up of fractures in the hospital devolves almost entirely upon the gentlemen who act as clerks to the attendant surgeons; and among the many other great advantages which a clerkship confers, in practice of medicine, pathology, practical surgery, and indeed every branch of the profession, are the almost daily opportunities they possess of managing cases of fracture, by which many of them acquire a degree of proficiency as relates to facility, neatness, effective and quick application of bandages, splints, &c., which the generality of practitioners have no field for obtaining, and therefore never arrive at, and which gives the fortunate possessor a great superiority in after life.

Comparing the limited extent of parts on which the extending and counter-extending forces bear in this method of Desault, and the large surfaces on which they act in the other plan I used, it may excite surprise there was not more pain in the former than the latter, and also that no inflammation of the parts pressed upon, or ulceration, or sloughing, should have occurred. In the one case the strong and constant pressure probably comes to tell principally on the prominent internal condyle, thinly covered by irritable soft parts; in the other, traction by the bandage at the foot is, or *should be*, diffused over the entire leg: and the perineum is, comparatively to the knee, so thickly covered with soft parts, while the band can be occasionally slightly shifted by the patient, that with one exception more than the most trivial fretting of the skin did not occur, and that exception entirely arose from the bandaging of an inexperienced substitute, who acted in the absence of the ordinary clerk.

It is less my wish to give elementary descriptions of the apparatus, and the method of application, than the practical points deducible from its adoption; it essentially consisted of Desault's plan, modified as described in the excellent Practical Surgery of Mr. Liston. A splint, with notches at the

extremities, three or four inches broad, of length sufficient to extend from nipple to ten or twelve inches beyond the foot, and of a bran pillow, of nearly corresponding breadth and length: there was likewise a perineal band stuffed loosely with fine carded cotton to about the thickness of the wrist, and to prevent it being soiled or wetted, covered with fine oil silk; a strong cotton roller, five or six yards in length, completed the apparatus. The pelvis being fixed by one assistant, another made gentle fatiguing extension from the foot, when a turn of the roller was applied below the knee, and carried with the greatest possible equality down over the leg and foot; from the dorsum of the foot, it was conveyed eight or ten inches beyond the sole, passed round the notch in the extremity of the splint, then again to the foot and leg, as far as the knee. In this manner the pressure and traction by each end of the bandage was so equally diffused over the entire surface of the leg, that uneasiness was seldom complained of, and the irregular form of the limb at the calf and ankle prevented the bandage from slipping. This method of applying the bandage for extension was found much easier for the patient, less liable to be displaced, and less apt to cause irritation over the instep or malleoli, than the padded band sometimes used; and answered all these purposes better when laid down without the accompaniment of compresses of cotton, which in place of defending the parts from pressure, were found to concentrate it so as almost invariably to cause pain, as a consequence restlessness, and had they been continued, the production of ulceration. I have lately seen used by one of the clerks of the hospital another plan for making the extension from the leg, which is well fitted to prevent any uneasiness, or at least to reduce it to its minimum, and which is at the same time very effective for the purpose. This is essentially the method adopted for obtaining a fixed point on the limb, from which to make extension in the reduction of dislocations. A stripe of strong cotton cloth, about three yards long, is prepared. The two ends of this are laid one on each side of the leg and thigh, the middle hanging sufficiently far from the sole to be hooked on the notch at the lower

end of the splint. The ends are then kept applied to the sides of the leg, by surrounding them and the member with a roller from toes to the knee; the remaining ends of the cotton cloth are now carried down outside of the roller, over the same course as occupied by the two other portions, and the roller, or better, a Scultetus, being again made to surround the limb, and the two side pieces, they are held sufficiently firm for the required degree of extension, while the pressure is so equally diffused that uneasiness and ulceration are entirely avoided. The splint, with the pillow on it, was now laid along the external aspect of the limb; the limb sufficiently extended, and coaptation of the fracture effected: the band carried under the perineum; its ends passed through the apertures or notch, and secured; and lastly, the splint was secured to the limb and body of the patient by bandage, so that the limb and trunk were kept in a straight line, and the extending forces acting in the same direction, displacement was effectually prevented.

In using this plan it is especially requisite to prevent the patient from carrying, (which he is much disposed to do) his trunk away from the splint, in order to relieve the uneasiness of constantly lying on his back. When this point is neglected, the trunk being carried inwards from the upper part of the splint, draws the superior part of the femur along with it; the upper fragment consequently stands at an angle with the upper extremity of the lower, and an external curvature is thus formed, shortening the limb, impairing its strength and activity, and of course occasioning deformity.

I have seen several much deformed limbs from this cause, which resisted all attempts to make them straight; a result which the supposed softness of the callus was expected to have permitted to be of easy accomplishment.

It is requisite to institute occasional examination for ascertaining whether the proper length of the limb in which the fracture is situated, be maintained. I have seen several modes tried for effecting this seemingly simple and easy matter; but I believe all the plans are inferior to comparing the length of the injured with that of the sound limb, while the one is laid along side the other, and while means are taken to

place the superior spinous processes of the pelvis perfectly transverse to a line falling through the centre of the body and between the limbs. If accuracy as to the direction of the limbs to the pelvis be not observed, I have ascertained by measurements on the skeleton that very erroneous conclusions may be arrived at.

Such was the mode in which we managed our simple cases, and after its adoption, as the more important points, our patients experienced greatly less discomfort, and as a whole, from the less motion to which they were subjected, had their fractures united in a shorter time than by the other method. Another not slight recommendation of Desault's plan was the ease with which it was managed by the attendant, compared to the other. In many instances, partly, in all probability, from the transverse direction of the fracture, any interference was not required after the first application: in none was more needed than an increase of the extension if upon measurement of the limbs any shortening was observed: whereas, when the other practice described was followed, almost daily taking down, renewed extension, and a troublesome, tedious re-adjustment, were required.

General or local medicinal applications were rarely required. The trivial excitement usually following reception of the fracture, commonly subsided in a few days under restricted diet, and the perfect quietude application of the apparatus ensured. Afterwards, full diet, and if circumstances dictated, porter, &c. were allowed, in the conviction that osseous reparation would be hastened and perfected sooner in a condition of system short of plethoric, and consequent risk of functional derangements, than when the patients were in a state of emaciation and debility.

Though having the advantages of substantial fare, still, from the want of exercise, and it may be also from respiring an atmosphere deprived of its due constituents by the crowded inmates of the wards, and contaminated by the emanations from burns, wounds, &c. the patients were almost universally pale, emaciated, and weak, at the expiration of their confinement. Such condition shewed the prejudicial effect of the confinement on the sanguiferous, muscular, and cuticular systems, and it

is not probable it was more favourable on the osseous: so that, to have restricted the diet would not only have protracted re-union, but have unfitted the patients for a longer time from being able to resume their employments.

As noted in the "Statistics," the cases of fractured femur were, one with another, seven weeks in the hospital. Even after the lapse of that time perfect use of the limb was far from being restored, and the following case, of which I have seen several examples, shews that osseous union was not near completion at the ordinary period of dismissal; points out the propriety of great care on the part of the patient; and that he should be admonished not to throw the weight of the body on the injured limb, lest the yet soft callus should yield, and shortening or curvature occur, for which, however unjustly, the surgeon would be held responsible.

CASE II.—R. S. was admitted in June 1841, for fracture of the femur two and a half inches above the knee: he was treated by the method with the three splints, and was discharged at the end of seven weeks. In a few days after, from one of his crutches sliding, he fell, re-fractured the femur at the former seat of injury, and was readmitted. He did not again leave the hospital until eight weeks had elapsed, shewing, what from *a priori* reasoning might have been questioned, that the period required for union was not under such circumstances in the least abbreviated.

CASE III.—*Fracture of femur accompanied by great swelling from extravasated blood.*

C. D., æt. 19, admitted May 1841. A horse on which he was riding, reared, and fell backwards upon the left thigh of the patient, fracturing the bone at the junction of the lower with middle third. The limb was four inches more in circumference than its fellow; the swelling extended from below knee to anterior superior spinous process, was said to have come on instantly after the accident; caused great and disagreeable tension, and was accompanied with lividity. The swelling prevented arterial pulsation from being felt, excepting behind inner ankle, where it was very feeble. The sudden occurrence of the

enlargement, and the discolouration, excited fear lest rupture of the main artery by the heavy pressure of the animal, or puncture of it by one of the extremities of the bone, had occurred, a circumstance of which Sir A. Cooper details a case, and of which I also had a fatal instance a few years since, which was witnessed by my friend, Mr. Thomas Gray. The limb remaining warm, discountenanced our first impression, and to facilitate gravitation, whether of serum or blood, and thus reduction of the size, the limb was placed easily on a double-inclined plane, covered with fomentations, and a purgative exhibited; as the pulse had re-acted, frequent doses of solution of antimony were given, and 15 leeches applied. The swelling in a few days began to subside; the aid of gentle pressure was called in: in a short time after Desault's apparatus was put on, and at the end of seventeen weeks the patient was discharged cured.

The sudden occurrence of the swelling, and the discolouration here, assure us that the symptoms were occasioned by extravasation, probably yielded from a vessel or vessels of considerable size, but whether from the main artery or not must remain uncertain, though from the recovery the affirmative is very unlikely. The tension was at one time exceedingly urgent, and excited so much discomfort to the patient, and anxiety to us, lest it should occasion interruption to the circulation, that we had some intention to incise. Averse, however, to run the hazard of converting the cavity containing the blood into a large and probably inflamed abscess, the member was elevated as described, when the extravasated blood gravitating to the lowest part, where it shewed itself by increased lividity, the symptoms speedily disappeared.

In this case union was long in being effected, and the patient was in the house for the long period of seventeen weeks. Stiffness and induration of the member existed for a considerable time, and the protracted confinement and those conditions were referred to the presence of blood between and around the fracture, and in the intermuscular fasciæ. In my case alluded to, where the femoral artery was punctured by the pointed extremity of one of the fragments, the patient was an elderly man.

From intoxication at the time of the accident, or as a consequence of the punctured artery, he was excessively restless, tossing the limb in all directions. Lividity soon supervened. An incision carried through the fascia was made in front of the thigh, exposed large coagula, but did not afford relief. The member soon became cold, pulsation in the posterior tibial could not be felt, and the patient died. Dissection exposed the artery punctured in its middle third, surrounded with large coagula, the muscles from groin to knee separated by blood, and the fragments so pointed and sharp that the fingers could with difficulty be placed in the cavity without risk of puncture or laceration. If the above condition could be easily ascertained, it becomes an important question how it should be treated. To expose the artery at the punctured part, insulated from its connections, and surrounded by large coagula, with the collateral vessels compressed by the blood driven among the muscles, and in addition to convert the case into one of compound fracture, would hold out little chance of success: to secure the artery above the supposed point of injury might not prevent escape of blood at the puncture, and great as the danger is from primary amputation in the thigh, such operation would, I think, be the least of the two evils between which we would have to choose. It is a most improbable supposition that in such circumstances the cavity in which the blood will be found shall become defined, the circulation in the limb continue, and a traumatic aneurism be formed, surrounding or communicating with the fracture; and that the case will advance so far favourably as to permit the ligature of the vessel as in the usual manner for aneurism. Still, no interference which can compromise retention of the limb will be justifiable until unquestionable signs of death of the member have shewn themselves.

It is unnecessary to dwell upon the occurrence of such cases, as shewing the danger of much motion in the conveyance of patients with fractures, and especially those of the femur at the junction of the middle and lower thirds, or of rude examination and change of position of the injured member, as thereby the comparatively thin layer of muscle or tendon between the bone and the vessel at that part may be

lacerated by the end of a sharp fragment, and the artery be punctured, as happened in the case detailed. The brittleness of the bones, and the consequent greater sharpness of the fragments in the aged, render them more likely to be the subjects of this dangerous complication, while they are the most unfit to bear up against their effects.

[To be continued.]

ON TUMORS OF CICATRICES.

By JOHN MACPHERSON,
Civil Assistant-Surgeon, Howrah.

(For the Medical Gazette.)

VERRUCOUS tumors of cicatrices are by no means rare among the natives of Bengal. They usually occur in the cicatrices of extensive burns, or in those left by the application of the actual cautery over the spleen, a practice almost universally pursued by natives in the treatment of enlargements of that organ. They are also sometimes found in the cicatrices caused by severe flogging. These tumors appear to have much the same character here as in Europe; they are only locally malignant; do not affect the general health for many years—not, indeed, until extensive ulceration is set up; and even then the bones or deeper-seated parts are rarely contaminated, according to my experience. The following stages of these tumors are distinctly observable:—

1st stage. One or more simple elevations of the cicatrix, or of part of it, quite soft, and a little smoother than the rest of the cicatrix. In this stage there is no pain, and the disease may never advance beyond it.

2d stage. Hardening and swelling of these elevations, forming one or two detached warts, perfectly smooth externally, and cartilaginous within: “when their section shews a firm hard structure, of a dense white colour, rising in a fibrous manner perpendicularly from the surface of the cutis.”* The tumors now generally begin to get painful, and advance gradually to the—

3d stage. When the tumors become a little depressed in their centres, become softer, more vascular and pain-

* Caesar Hawkins' Lectures on Tumors, MED. GAZETTE, vol. XXI, p. 994.

ful, and shew a tendency to run into each other.

4th stage. The tumors begin to ulcerate and spread at their edges, and bear all the usual characters of scirrhus.

The foregoing division into stages is of course to a certain degree arbitrary, and only meant to be descriptive of about a dozen cases which have come under my notice. Patients never apply for relief before the end of the second, or beginning of the third stage; in either of these stages excision appears to offer a certain cure, and is far more satisfactory than the application of corrosives. The following cases are chiefly illustrative of these two stages.

CASE I.—A convict complained of three small tumors over his right scapula, which he attributed to a flogging received seven or eight years before. They were oval, smooth, and hard to the touch, about the size of crown-pieces. They were slightly flattened at the top, and had begun to be so painful as to interrupt his sleep. They were excised; and the skin round, and the cellular tissue beneath them being quite healthy, the wound healed readily. When cut into the tumors were white, bloodless, and devoid of vascularity; they were hard, fibrous, and displayed all the usual characters of scirrhus in its early stage. Another convict had similar tumors from a similar cause, but in a less advanced stage, and not painful.

CASE II.—An old woman presented herself with a warty tumor about four inches long, in the cicatrix of an old burn, on her left fore-arm. It consisted of three flattened tumors, which had run into one another, and were advancing towards ulceration, one or two points near the surface having become vascular. As it was exceedingly painful, she had it excised at once—now fourteen months ago. The wound healed well, and she has not returned. The tumors in this case resembled those in the last, but shewed more tendency to vascularity.

CASE III.—A man shewed himself with an immense cicatrix of a burn, extending in front from the shoulder to the wrist of the left arm. At the bend of the elbow there was a very large, raised ulcer, about six inches long and four broad, with a profuse sanious discharge. Even in this advanced stage

the surrounding parts seemed quite healthy, and it was proposed to excise the cancer, and save the amputation of the arm. The patient, however, would not submit to any operation, and went away without having any thing done.

CASE IV. was a large, broad, raised ulcer, in a man of 70, just over the right mamma, about 2½ inches long, and 2 broad. It exactly resembled the cancers of cicatrices which I had met with, but no history of any former cicatrix could be made out. Various escharotics were applied with temporary relief; but as the cancer was spreading, and the neighbouring skin was perfectly healthy, it was thought best to remove it with the knife, which was accordingly done, and followed by a complete cure. In this, as in all the cases I have met with, the cellular tissue beneath the tumor was perfectly healthy.

CASE OF COPPER-COLOURED SYPHILITIC ERUPTION AFFECTING THE CONJUNCTIVA.

BY ALFRED SMEE, F.R.S.

(*For the London Medical Gazette.*)

As far as I know, there is no record of specific eruptions attacking the conjunctiva, but an instance having recently occurred at the Central London Ophthalmic Hospital, it becomes my duty to record it.

The subject of the affection was a respectable married female, the wife of a traveller, who applied at the Charity to be relieved of a small ulcer which existed at the edge of the eyelid. From its appearance I immediately recognised its specific character, and upon inquiry, I learnt that both husband and wife had laboured under syphilis for a period of two or three years. At that time I put her upon the general antimonial treatment, described in the MEDICAL GAZETTE, and the ulceration speedily healed. At this period there were also numerous copper-coloured spots over the skin, which I supposed she thought of but little consequence, as I lost sight of her as soon as the ulceration had healed.

After a short interval she returned again, and stated that her eye was somewhat uneasy, and that she feared

a return of the malady: on examination the conjunctiva below the cornea presented a spot a little smaller than a silver penny-piece. This spot appeared formed by the conjunctiva itself at that point being swollen; in fact, the surface was obviously raised, and the colour changed to that of a cupreous hue, somewhat similar to the colour of the spots of the skin, but considerably lighter: this spot was not absolutely opaque, but semi-transparent, and it gave the idea that the conjunctiva at that part was swollen in its substance, and tinged of a copper colour. It presented no unusual vascularity; in fact, I do not know that I should be justified in asserting that there was a single vessel either increased in size or added in number to those existing in the normal state. The copper colour, then, had no immediate reference to the vessels, and was due to the part exhibiting the syphilitic stain; a phenomenon by no means understood.

This eruption must be considered analogous to those of measles, small-pox, and scarlet fever, which commonly attack that membrane; but perhaps it is even more analogous to that of purpura, which often affects the conjunctiva, of which a very beautiful example occurred at this Charity last summer. The spots of the two diseases, although presenting the distinct characters appertaining to each malady, were perfectly analogous; that of one exhibiting deep purple circumscribed spots, that of the other a copper-coloured, circumscribed spot.

I remember to have seen some time since pustules on the conjunctiva, associated with pustules on the skin, which appeared to have their origin in the syphilitic virus, but up to the present time I have never before seen the copper-coloured eruption to affect this membrane.

There is no particular practical importance to be attached to this malady, for it causes very little trouble of itself, and requires no treatment apart from that required by the system generally. In this case the antimonial treatment was employed, but as the progress was not to my mind sufficiently rapid, I tried the iodide of potassium, giving four grains three times a day, under which treatment it declined, and the patient discontinued her attendance.

The occurrence of this eruption is to

me exceedingly interesting, inasmuch as, being the first case of the kind which has been narrated, it opens the door for further investigation. The affection, in this instance, occurred in a case where the poison had run its own course for years, without regular treatment, and therefore the rarity of the affection may be increased by this circumstance of itself being unusual. My motive in recording this case is to direct the profession to its occurrence, in the hope that by a multitude of observations we may ascertain to what extent this disease attacks the conjunctiva.

7, Finsbury Circus,
Nov. 20th, 1844.

NOTICE
OF

THE MEDICAL ORGANIZATION,
STUDIES, &c. IN ITALY.

To the Editor of the Medical Gazette.

SIR,

AT the present juncture, when public attention is so strongly directed towards the proposed alterations in the medical profession, the accompanying notice of the medical organization, studies, &c. in Italy, will be read with interest, and perhaps with advantage. It is chiefly translated from the Italian edition of M. Combé's work, "*Della Medicina in Francia e Italia*;" with notes by Professor De Renzi, and enters more fully into the subject than I have done in my work on the "*Continental Medical Institutions*," which restricts itself more particularly to the practical part of medical science.—I am, sir,

Your obedient servant,

EDWIN LEE.

Upper Southwick Street,
Oct. 16, 1844.

The direction of medical affairs in Italy is more or less under the superintendence of the respective governments. In some instances the various administrative acts relating to the public health emanate directly from the minister; in others, from a commission or magistracy; or from an individual distinguished by his superior attainments and knowledge. Such are, on the one hand, in Piedmont, the supreme and royal direction of public instruction; at Parma, the grand master of the University; at Rome, the holy congregation

of studies, presided over by an arch-chancellor; at Naples, the junta of public instruction, with an archbishop at its head: on the other hand, there is the *protomedicato*, as at Genoa, Turin, Milan, and in Tuscany.

The practice of the healing art is divided in Italy among different kinds of practitioners, which have each a separate office. In the first place there is the physician, who, after belonging five or six years to the faculty of physic, and after serving two years as assistant in the clinical ward of an hospital, obtains the right to practise. Next, is the surgeon, who after four years of studies analogous to those of the physician, and after a certain period of trials and special studies, is considered capable of dedicating himself exclusively to the operative department. Afterwards comes the phlebotomist, who is restricted to the lower department of surgery, and corresponds to the *officier de santé* in France.

In the second order are the apothecaries (*farmacisti*), upon whom are imposed several conditions of guarantee and of capability, including the deposit of a sum of money (about 4000 francs): the midwives, oculists, dentists, and those whose business is restricted to bleeding, the application of leeches, blisters, cupping, &c. The druggists and herbalists form the lowest steps of this medical ladder.

The *protomedicato* constitutes a particular magistracy formed of a medico-chirurgico-pharmaceutical council, presided over by a chief who has the title of protomedico. It is composed of an equal number of physicians, surgeons, and apothecaries, and holds three sessions annually; one of medicine, one of surgery and obstetrics, and one of pharmacy.

The principle of the protomedicate, as organized by a regulation of the King of Piedmont, dated the 16th of March, 1839, rests upon the direct and legal superintendence of all those who practise medicine or surgery, wholly or in part, and the veterinary art; in order that each of the members of the medical corps should restrict himself within the limits of the department of the profession for which he has received a qualification.

The attributes of this body are still more clearly defined by a decree of

Maria Louisa, Duchess of Parma, as follows:—

1st. To decide upon the capabilities of those who seek to be admitted to practise any of the branches of the art of healing; as also to judge of the degree of knowledge of those already possessing a diploma.

2d. To maintain discipline among these latter; to censure, and to punish them when requisite.

3d. To prevent, and to reconcile, the disputes which may arise between physicians, surgeons, &c. regarding the rights of their respective professions.

4th. To obviate grounds of complaint on the part of patients; to approximate to each other the discordant parties; to punish those of the medical body who are guilty of an infraction of the regulations; but solely in those respects of which the ordinary tribunals cannot take cognizance.

5th. To express an opinion with regard to the pretensions and the compensation of physicians, surgeons, apothecaries, and midwives.

6th. Lastly, to watch that each individual exercise his profession in a legitimate manner, and according to the regulations.

Before granting the *exerceat*, the protomedicate requires, in addition to the other certificates, that the physician should give proofs of his competency at the bed-side of three different patients, by examining, and writing the history of three different diseases, indicating their causes, symptoms, progress, diagnosis, and mode of treatment; that the surgeon should perform two operations upon the body—at three different times; and that the apothecary should make up eight preparations, or pharmaceutical compositions.

The preceding account sufficiently shows the difference between the protomedicate of Piedmont and that of Parma; the former is simply a magistracy of police destined to prevent usurpations, and to keep each one in his proper place: the latter is at the same time a directing body, for the more efficient prosecution of studies, and affords a guarantee that the knowledge of members has been attained in the bosom of the faculty.

The merit of having more fully organized the institution in this respect belongs to Professor Tommasini, to

whom is likewise to be attributed the regularisation of an improved system of vaccination. The practitioners whose business it was to propagate vaccination formerly received a certain sum for each child subjected to the operation, and Professor Tommasini thought he perceived, in the lists sent to him in his capacity of president of the protomedicate, that many of the children inoculated did not present the signs of a true vaccination. He consequently established a body of young physicians for the purpose of superintending the vaccinators, who, when the lists were about to be made out, visited the houses where children had been vaccinated, and gave a regular certificate of their actual condition, and of the normal or anormal appearance of the eruption. Hence resulted a greater regularity in the service, the certainty of the reward being granted in proportion to the real service performed, and the advantage of bringing before the public young men of talent, who, after three years, gave place to others who had distinguished themselves, thus keeping up a salutary degree of emulation among them. In no part of the world, perhaps, was the discovery of Jenner received with a greater degree of faith and enthusiasm than in Italy, and the government sought by every means to prevent the ravages of the small-pox, and favour the progress of vaccination. In Milan, for instance, if parents refuse to have their children vaccinated, a *procès verbal* is signed by the vaccinator, the curate of the parish, and the syndic of the district, stating the opposition that has been made, and this is sent to the provincial delegation. Charitable institutions do not grant assistance to those who cannot shew a certificate of having been vaccinated. The curates are obliged to send every three months to the vaccinator of the district a list of the children born and baptized in their parishes; to read from the pulpit every three months the names of those who have died from the small-pox, and at the same time to remind parents of their duties towards God and the Prince, which command them not to omit to avail themselves of so great a benefit as vaccination.

When an individual is attacked by the small-pox, the head of the family, and the physician or surgeon in attendance,

are bound to make an immediate declaration thereof to the municipal authority under a penalty of 100 francs, or a fortnight's imprisonment. The administration causes to be placed over the door of the house, the following inscription in large letters—"The small-pox is in the family of ———— residing in this house." All those who have had communication with the patient are shut up in the same house until a cure or death ensues; the body is carried to the burial-ground without being accompanied by a priest, and is buried without funeral ceremonies in a spot apart.

According to the new regulations issued by command of the King of Naples, all those who have omitted to avail themselves of vaccination are incapacitated from enjoying the sovereign munificence: petitions are not received by the ministers, nor in any charitable institution, unless accompanied by a certificate that the individual has been vaccinated. The administrators of hospitals are bound to cause children to be vaccinated in the month following their admission. Directors of colleges, ecclesiastical, civil, or military, are prohibited from receiving any pupils who have not been vaccinated.

A central Royal Vaccine Institution is established in the capital, composed of ten ordinary members, and two super-added, who have under their orders twelve ordinary vaccinators, and as many extraordinary; as also six *employés* for the correspondence. Each vaccinates gratuitously at his residence daily. Every three months vaccine virus is sent to the provinces, from the minister of the interior, and its receipt in a good state is acknowledged by the provincial vaccinators. The children vaccinated must be brought several times to the vaccinators, in order to ascertain that the effect is produced.

Vaccine commissions exist in the chief town of every province and district; which are bound to act according to the instructions transmitted to them, and to endeavour to diffuse the propagation of vaccination in their respective localities.

All *employés*, and those who live at the expense of government, must have their children vaccinated. The clergy are charged to preach to the people re-

specting the usefulness of vaccination, and the duty which is imposed by God and the King upon each father of a family to preserve by its means from sickness the lives of their children.

The vaccine junta of each district causes midwives to be instructed and convinced of the utility of vaccination, and obliges them to promote its practice as much as possible. The junta meets every month to ascertain that its regulations are obeyed, and in what degree vaccination has prospered or has declined.

These are some of the principal points of the regulation issued in September 1838; and it appears from the statistical returns, that while in France, where vaccination was introduced at an earlier period, out of a population of 32,000,000 individuals, 495,450 children were vaccinated, whereas in that part of the kingdom of the two Sicilies nearest to the rest of Italy, the population of which amounts to 5,720,000 inhabitants, as many as 180,000 are every year subjected to this preservative medium.

M. Combé states, that notwithstanding the bright example furnished by Tommasini in the greater extension of the office of protomedicate, this institution has fallen somewhat into disuse in most parts of Southern Italy. This, however, is denied, with respect to Naples, by Professor de Renzi, in the notes to M. Combé's work. In Lombardy it is now concentrated in one individual, termed Protomedico.

Civil Practice in Lombardy.

The sanitary-administrative organization in the kingdom of Lombardy rests upon a Councillor-Protomedico; then come the physicians of delegation, the district physicians, and the municipal physicians.

The councillor Protomedico is equal in dignity to the other official councillors in Austria, holds his administration in the same Government Palace, has a vote in the central assembly, presided over by the governor and the Aulic councillor, even when other than medical matters are treated off; and once a week he submits to the others the consideration of those matters which relate to the public health. His propositions, like those of his colleagues, are admitted, modified, or rejected, ac-

cording to the majority of votes. The orders issued from the cabinet of the Protomedico, termed the minister of public health, are executed when countersigned by the governor. He presides over all affairs which relate to the economical and sanitary administration of the hospitals; maintains the regulation and the discipline of the studies which refer to the exercise of medicine, surgery, pharmacy, and the veterinary art; watches over the service during the prevalence of epidemic or contagious diseases; regulates the nominations, promotions, rewards, and punishments of the medical body, the proper maintenance of the cemeteries, and, in fact, upon him depend the guarantees for the health and physical well-being of the population.

For the expedition of affairs, the Protomedico has at his disposition a secretary, vice-secretary, veterinary superintendent, and several assistants. He has a salary of from 6500 to near 8000 francs annually, exclusive of other emoluments (which may amount to 1000 francs). The secretary and the vice-secretary are paid like those of the other ministers.

The territory of Lombardy is divided into nine provinces, of which each possesses, in its chief town, a royal delegation, destined to watch over and provide for the interests of the district, and of the dependent communes. Attached to each delegation is a *medico-reale*, who enjoys similar privileges in the province to those of the Protomedico in the capital—being next in rank to the royal delegate, to whose authority he is subordinate, and by whom his orders must be countersigned. Next to the *medico* is the *chirurgo-provinciale*, who possesses the degree of Doctor, but is dependent upon the former: his office is more particularly to supply the place of his superior while he is on his annual tour of inspection of all the public medical establishments, and of all the pharmacies within his district. The *medico-provinciale* has an annual salary of 1500 francs, and receives besides 36 francs for each pharmacy which he visits. The surgeon receives 1000 francs a-year. The assistant has no salary, but the expectation of an appointment, or a lucrative promotion.

The district physician is selected

from among the great number of those who are residing in the subdivisions of each province, termed districts. His office is solely to encourage, and to practise, vaccination in the communes of his district. He is applied to in preference in cases of urgency, of public calamities, or of orders emanating from the supreme authority. He receives an annual recompense. The *medico-chirurgo delegato* is chosen and nominated by the majority of votes of the magistrates of one or more places, subject to the approval of the Royal Provincial Delegation. His business is chiefly the treatment of the poor of the villages or boroughs; but although he is obliged to attend and treat all the poor sick of the communes by which he is paid, he need not refuse his assistance to richer patients when consulted by them; he must inform the Delegation of all the medical cases which present an epidemic character: it is, moreover, his business to inform the authorities of all unqualified persons who may attempt to practise medicine, surgery, or obstetrics. His salary varies according to the extent of the commune, the number of poor and rich inhabitants, the fertility, and consequently the richness, of the country: it may be estimated at from 800 to 2600 francs; to which must be added the profit derived from the treatment of, or operations upon, those patients who are above a state of indigence; these amount, in some localities, to 4000 or 5000 francs, or upwards.

In many places the chirological administration is distinct from the medical; there are then two individuals occupied. In other parts, a public service of obstetrics is annexed, for rendering assistance to poor women in labour. The obstetrical medico-chirological administration is differently organized, according as it applies to the poor of the town or in the country. Of the former, those who cannot be sent to the hospital are visited gratuitously in their houses by practitioners termed *medici della corona reale*, who attend in different parts of the town, and receive a salary from the hospital funds.

The *medico-municipale* exists only in communes of the first class, and his office consists in visiting public women, and houses of prostitution. The tri-

bunals and the theatres have also their physicians, who have to give certificates in cases of disease, to verify the commission of criminal acts, draw up reports, &c.

[To be continued.]

RECORD OF CASES.

By THOMAS MAYO, M.D. F.R.S.

Physician to the Infirmary of St. Marylebone.

[Continued from p. 148.]

Chronic cases, treated with partial or entire success, in which morbid changes of the cerebral or spinal system have existed, or have been threatened.

JULY 13, 1820.—Miss R., a young lady aged 24, of moderate height and embonpoint, well-formed, of a dark complexion, of an even temper and strong intellect, complained of a general sense of oppression, heaviness, tightness, and throbbing of the head; a wearing sensation, with heat at the bottom of the back, amounting sometimes to excessive pain; scanty and high-coloured urine. The catamenia are regular; appetite good; tongue slightly furred. It appeared that these symptoms had been recently aggravated by the use of the chalybeate waters of the place (Tunbridge Wells), which had disagreed with her. The catamenia, though regular, were far from profuse; the latter state, whenever it occurred in the subsequent treatment, always made her worse. The same result followed excessive action of the bowels, which, however, required frequent mild aperients. Walking, and even airing in her carriage, were followed by a sense of weariness and feebleness inconsistent with her age and muscular development. At the right side of the lowest lumbar vertebra I found a space, about the size of a shilling, extremely painful on pressure, which left also a very enduring pain.

Oct. 18th.—The bowels have been kept gently open by Compound Extract of Colocynth and Pil. Hydrarg.; doses of Potassi Acetat. ʒj. e Mist. Camphoræ, ʒj.; Infus. Sennæ, ʒss. occasionally given, and leeches applied to the loins, always, however, with a consequent depression of power, which forbade their frequent use. The patient has been recumbent a large portion of each

day, and taken airings in an easy carriage. There is less uneasiness of head and inability to apply the mind. The urine is increased in quantity; but the wearing sensation at the loins, though lessened, continues with occasional exacerbations, under which it passes down the thigh and leg. The lower limbs have become more powerless; there is a rolling and uncertain movement in the legs, which cross each other involuntarily in walking; and on the occurrence of one deficient period, the paraplegic state greatly increased. There is, however, neither numbness nor rigidity, nor spasmodic action, and the spine itself is perfectly normal.

It now appeared to me expedient to add to recumbency the benefit of some local drain, in relation to these last symptoms. Leeches, as observed, benefitted, but weakened unduly. The peculiar constitution of the patient's mind rendered issues or setons inexpedient. Local examinations and appliances of this kind were likely to complicate the case; for very obstinate constipation and retention of urine had recently ensued on an unavoidable exposure of her person, with reference to the question whether the hip-joint might be in fault. I determined to carry out a course of small blisters, one applied every second day, on or near the painful point on the right side of the lowest lumbar vertebra. When this had continued three weeks, I find in my notes that the power of walking with crutches or sticks had materially increased (I allowed her this exercise for a limited time each day), and the degree of weariness ensuing on exercise had materially diminished. The bowels required mild aperients almost nightly; and it is observed that the patient is always best on those days which succeed the exhibition of some calomel added to the pill.

The blistering system commenced in December, 1820. During the first two or three months of its continuance, whenever the intervals between their application were much lengthened, I found reason to regret this. But on July 16th, 1821, I find it noted that for the last month these intervals had been six or seven days without any recurrence of heat and weight in the lumbar region, which had taken place previously whenever the repetition of

the blister had been thus delayed. This drain, it is to be observed, produces no depression; but the effect of an active aperient continues as depressing as at first described by me. Mineral acids were occasionally given during this time. The following agreed admirably:—

℞ Infus. Cascariæ, ʒiss.; Tr. Cinna-
mom. Co. ʒj.; Syrup. Rheilor. ʒss.;
Acidi Nitrici Muriatci, aa. gtt. ij.

Gradually the blisters were discontinued, and the patient left Tunbridge Wells, at the end of September, free from that local heat and tenderness, as well as pain, and from the paraplegic symptoms, for which they were adopted.

In justice to the above plan, I must observe that the absence of carious disease in the bodies of the vertebræ was presumed; otherwise a deviation from recumbency would not have been permitted by me.

This young lady had been sent to the place where I saw her in reference to its chalybeate waters. The diagnosis, in regard to such treatment at that place, is not easy, where congestive symptoms coexist with feebleness in a nervous temperament. The chalybeate, however, is generally mischievous in such cases, when the secretion of urine is scanty and lateritious.

In the following case a similar procedure to that which succeeded with Miss R proved equally useful.

June 8th, 1823.—I was sent for to Miss Bowra, a farmer's daughter, aged twenty-five, in the neighbourhood of Penshurst, to meet Mr. Douthwaite, of Tunbridge. I learnt that seven years before she had been attacked by severe pains in the head, for which V. S. and other remedies of that class had afforded no relief; but in the course of time they gradually subsided. In the January of the present year these pains had returned with much severity; and entire paraplegia, in regard to voluntary motion, had supervened. These, and the following facts, I find noted by me, viz., a small and languid pulse, continually recurring spasms; intense sensation of heat of head; frequent hysterical sense of suffocation; flatulent distension of stomach after food; extreme emaciation. The plan laid down under those circumstances was as follows:—

Emplast. Lyttæ lumbis quâque septimâ.

R Pil. Hydrarg. gr. iij.; Ext. Colocynth. Co. gr. iij.; Capsici, gr. j.; Rad. Ipecac. gr. ss. o. n.

R Mist. Camphoræ, ʒvss.; Sp. Ammon. foetid. ʒiij. 4ta pars bis quotidie.

I saw this patient once only, but was subsequently informed by Mr. Dowthwaite that repeated applications of blisters to the back, mild mercurials, and adequate aperients, had completely cured her.

The following case, though widely different from the above, falls under the general head which I propose to illustrate.

The Rev. R. S., aged 37, of a pallid countenance, but strong, short figure, consulted me in February, 1838. He complained of inability to walk, or take any exercise, from vertigo and languor; of a fixed pain, and sense of obstruction, in the occiput, and uneasiness and numbness in the loins. His utterance was slow, and very laborious; and I ascertained from his friends that complaints which he also made of growing incapacity for business, were not exaggerated, whatever the cause might be. He was a sensible man, of an even temper. I ascertained that in early youth some evil habits of an enfeebling nature had been indulged in. He was a married man without children, and lived in the country.

Sumat. Pil. Hydrarg. Sub. C. gr. iij.; Pil. Galbano, C. gr. v. o. n.

R Sp. Ammoniacæ Succinat. ʒiss.; Aquæ, ʒvj.; 4ta partem ter quotidie.

R Ext. Co'ocynth. C., Rhei, aa. ʒ; Ext. Hyoscyam. gr. x.; in pil. x. divis. j. vel ij. p. r. n.

This course was pursued, with slight modifications, to the beginning of May, and was attended by the greatest relief of all his symptoms. Successful treatment benefits cases of this kind as much by the hope which it inspires or restores, as by its direct physical effects. No change was made in the general habits of Mr. R., which could explain his cure, independently of the medical measures. I may add, that I have often seen this gentleman since in the enjoyment of good health.

[To be continued.]

MESMERISM APPLIED TO SURGICAL OPERATIONS.

To the Editor of the Medical Gazette.

SIR,

ALTHOUGH in your articles upon the subject, you have expressed an opinion adverse to the pretensions of mesmerism, I suppose you do not intend following the dogmatical and unphilosophical course pursued by a cotemporary, of closing your columns to all discussions respecting it. I shall feel obliged by being allowed to address a few words through them to an important portion of the profession, among whom, I believe, the GAZETTE especially circulates—the hospital surgeons.

There are from 50 to 60 of these gentlemen attached to the metropolitan institutions alone, and I have not heard that even one of so large a number has employed the facilities which the charity with which he is connected may afford, in investigating the claims of mesmerism to the power of rendering persons insensible to suffering during the performance of surgical operations. Is this right? I humbly think that it is not, and that equally whether the alleged fact be true or false. The suffering attendant upon an operation is of so truly a terrible character, that whatsoever seems to offer but the shadow of a hope of even mitigating it, should be seized upon with avidity: and a credulity that engages in the essaying of many appliances to this end, which in the event may prove worthless, is far less to be condemned than unyielding scepticism, which forbids even the bare trial of such as might by possibility prove of service. It seems to me a very strange procedure, at the present day, to condemn that by *à priori* reasoning alone, to which the infallible test of experiment has not been applied.

Statements of the possession of this power by mesmerism have now been long and frequently made, and actual demonstrations have been repeatedly appealed to. The proper answer to these is not an impeachment of the veracity of the narrators, or charging them with collusion—and that in instances where prior respectability, and the absence of motive, alike render it improbable; it consists in the repetition of the experiments upon an en-

larged scale, and under circumstances which would render deceit of any kind impossible. By neglecting to institute such a series of experiments, the hospital surgeons have, to use the mildest terms, shewn a culpable apathy, and a want of a due recognition of the responsibilities of their position in the profession. For, supposing, sooner or later, the fact turns out to be true, as stated—which, to say the least, is not *impossible*—how will the amount of needless suffering inflicted between the period of its enunciation and the adoption of practices consequent upon its recognition, be justified to the mind of a conscientious man? On the other hand, supposing it proves an untruth or a delusion, is it of no importance that the public mind shall become disabused upon so vital a point, and definitively assured that those to whom it has intrusted life and limb have neglected no opportunity of alleviating suffering humanity?

In the very nature of things the experiment must sooner or later be effectually tried; but it seems a far more gracious circumstance that it should spontaneously originate with the profession, than that it should be forced upon us by the pressure of public opinion. The only difference arising from delay will be, that the experiment must be commenced with a different class of persons. The poor hospital patient must submit to things as he finds them; but the wealthy and informed patient will naturally insist that this prospect of an alleviation of suffering during his terrible emergency shall be essayed. Speaking for myself, I can certainly say, that were I unfortunate enough to require the performance of a surgical operation, I should feel most desirous of endeavouring in this way to obviate some of its horrors.

As to what degree of truth may exist in the doctrines of mesmerism, I do not profess to offer any opinion, being, in fact, very ignorant upon the subject. The few experiments I have witnessed have not been of a satisfactory character; and I believe I am as sceptical as most persons as to the ultra-pretensions of the professors of the art. I think much good would have accrued if, long ago, a searching investigation into the whole subject had been undertaken by a body of scientific and unprejudiced men, for the purpose of

deciding which, or whether any, of these pretensions possessed any foundation in fact.

However, this has not much to do with the purport of this letter. I wish in it solely to call attention to the urgent necessity, upon the part of those whose opportunities are so abundant, of instituting the necessary researches as to whether the procedure known as mesmerism does, or does not, possess the power of preventing suffering during surgical operations. *Let the experiment be fairly tried.*

Were our medical corporations constituted such as the wants of society require they should be, appeals of this nature would be uncalled for, or rather would be anticipated. The profession, harmoniously organized, might become a powerful instrument, in its corporate capacity, for the achievement of great benefits regarding all questions of public health; and inquiries which legitimately belong to it would not in future be utterly neglected, or, as in the case of various others, be superintended by Poor-Law Commissioners, whose only qualification for these supernumerary duties consists in their happening to possess so enlightened, benevolent, and indefatigable an individual as Mr. Chadwick for their Secretary.

I would suggest, that a committee of hospital surgeons be appointed for this important investigation; and I have no doubt that their report, if founded upon a patient, deliberate, and candid examination into the whole matter, will prove decisive not only with the profession, but with the public at large.

I am, sir,
Your obedient servant,
JOHN CHATTO.

Great Coram Street,
Nov. 25, 1844.

ANALYSES AND NOTICES OF BOOKS.

—
“L'auteur se tue à allonger ce que le lecteur se tue à abréger.”—D'ALEMBERT.

—
A Complete Course of Meteorology, by L. F. KAEMTZ, with notes by C. MARTINS; translated, with notes and additions, by C. V. WALKER, of the Electrical Society. 12mo. pp. 598. London: Bailliere.

At this season of the year, when the press teems with Almanacks of every

kind, from the carefully calculated "Nautical Almanack," intended to guide our enterprising mariners in their course through the trackless deep, to those of Partridge and Moore,—which are as aptly calculated to mislead those who put their trust in them, as were those in the time of Ben Jonson, who, in *Every Man out of his Humour*, makes a miserly character (Sordido) buy up all the wheat on the faith of their predictions of six weeks bad weather after St. Swithin's day, and then hang himself because the harvest was abundant, and the poor had plenty,—it is gratifying to find a work which seeks to explain the phenomena of the weather by well-ascertained data, and cautious induction. Professor Kaemtz was well prepared for the task he had undertaken, having devoted many years to sedulous observation, and having been long engaged in giving lectures on Meteorology; the present work being a summary of his Course, first at Halle, and subsequently at Dorpat. He is farther fortunate in having had his work translated into French, by Professor Martins, of Paris, a gentleman who has had a most extensive opportunity for acquiring a knowledge of climate, being practically acquainted with every climate which prevails between the summit of Mont Blanc, at which elevation he stood so recently as August last, and the 79° of N. L., which he reached, as a member of the French Commission of Observation, in 1839, from which he returned by land, while a great many others accompanied the ships on their homeward voyage. Most fortunate of all is the work to have found for its translator into English a gentleman so well qualified for the task as Mr. Walker, who had been employed to complete Lardner's *Manual of Electricity*, for the Cabinet Cyclopædia, and has subsequently discharged the duties of editor of the *Electrical Magazine*, an occupation well fitted to place him *au niveau* of all the recent observations and discoveries on the subject. Thus we have a work combining the knowledge of three most competent writers, the whole most methodically arranged and skilfully digested. It begins in so plain and intelligible a manner, that the veriest tyro can encounter no difficulty in following it step by step.

It would be out of place here to enter into an examination of the various sec-

tions of the work, but every one must feel that it is a subject intimately connected with our avocations, when the medical profession is viewed in its true and exalted character, and strives to prevent as well as cure diseases.

The connection of certain forms of disease with a certain constitution of the atmosphere is universally admitted; yet we are far from possessing precise knowledge on this important point. Lengthened observations are required before any inferences of value can be drawn; and it is less extraordinary than ordinary phenomena which should be recorded. The former are not without their use. Should any marked increase of the weight of the atmosphere, like that recorded by Dr. Prout, which he observed for six weeks previous to the outbreak of the cholera in London, in 1832, prevail, we might reasonably expect, we trust not that fearful visitation, but probably some other formidable epidemic, and take timely measures against its incursion. Some other interesting instances are given by Dr. Holland, in his *Medical Notes*, ch. xxviii. "On the Influence of Weather in Relation to Disease." In this Journal, (vol. xvii. p. 866,) we cited some striking cases, especially those alluded to in an able paper on *Medical Topography*, in the *Edinburgh Medical and Surgical Journal*, for April, 1821. Mr. Addison, of Great Malvern, has likewise furnished some apposite instances, (*Medical Gazette*, vol. ix., p. 752.) These, we hope, will enlist medical men in the cause, for, as Professor Kaemtz remarks, meteorology is a science which can advance only by the co-operation of a large number of zealous and persevering observers. That the number of these will be increased by the perusal of his book, we cannot doubt. Let our readers procure it, and we stake our character for accurate prognostication, they will commence observations, and make careful records from the first of January, to which we are drawing near, and which constitutes the appropriate time from which to start.

MEDICAL GAZETTE.

"Licet omnibus, licet etiam mihi, dignitatem
Artis Medice tueri; potestas modo veniendi in
 publicum sit, dicendi periculum non recuso."

CICERO.

THE MEETING OF GENERAL
 PRACTITIONERS IN MEDICINE
 AND SURGERY OF THE CITY
 OF WESTMINSTER.

WE cannot help regarding this as by far the most important public meeting which has yet been held in connection with the subject that has engrossed the professional mind for so many months past. The gentlemen who took part in the proceedings, were all of the highest respectability, and of the first standing as family medical attendants, of probably nine-tenths of all who people the most opulent quarters of London. The proceedings themselves had a character which stamps those who took part in them as men of sense and firmness; of talent combined with knowledge of business; and then the cause they advocated has so much of right and reason in it, that we apprehend it will be found very difficult to hinder them of the object they have at heart: the "*Incorporation of the General Practitioners of England into a distinct College.*"

Our views of the propriety of this step are known; we do not think it the best thing that *might* be done; but as we said, some short time ago, in our notice of the "Marylebone Manifesto," if nothing better *is* done, we are not sure that it may not prove the right measure after all. And so it is likely to turn out. Nothing better *has* been done: the College of Physicians are silent; the Council of the College of Surgeons maintain their attitude of hostility to the great body of their members*, and

* According to the vulgar report, the Court of Examiners have actually been rejecting several members of the College of "eight years standing," who had presented themselves for examination as candidates for the Fellowship! as if

we do actually begin to see that there is nothing else for it than the incorporation of the general practitioners of England with an independent College. The legislation that is perpetrated in connection with the medical profession at this time, and we take it for granted that some legislative enactment must now be made, for we cannot be left in the state of chaos into which we were thrown in the beginning of the autumn—the legislation, we say, that now takes place in reference to the medical profession, must recognize the General Practitioner; he is, in fact, the oldest representative of the medical profession in these kingdoms, and as Mr. Fuller well observed, "was recognised before either the College of Physicians, or the College of Surgeons, had an existence."

Our own aspiration has always been that the medical profession might be assimilated to what it is on the continent. That there might be one body, consisting of two classes of practitioners: Physicians and Surgeons with a common title, a common education, common qualifications, and a common place of assembly, the department followed being the result of individual inclination and free-will, in each particular instance; and that these practitioners of medicine and surgery should prescribe, and that their prescriptions should go to the chemist or pharma-

they cared not to say that a man might be good enough to be entrusted with the limbs and lives of the community, but was not good enough to have a voice in the election of a member of the Council from which he had his certificate of general competency. Surely the logic we learned at Marischal College was good logic, when it taught us that a minor was always included in a major proposition: if I am worthy to take off A. B.'s leg, or to cut down upon and secure the artery from which C. D., having wounded himself in the leg, or thigh, or arm, is bleeding to death, surely I am not unworthy among five or six hundred others, of saying aye or no to a proposition, the extent of responsibility involved in which is, whether or not E. F. shall have a seat in an administrative Council made up of twenty-four? But the Court of Examiners of the College of Surgeons—who probably never studied logic at Aberdeen—do not seem to think so; and taking the man, whom eight years before they had pronounced competent, again upon trial, they now pronounce him incompetent.

centist to be compounded. This constitution of the medical profession, it is certain, cannot be accomplished in England at the present moment; we have Physicians, Surgeons, and General Practitioners, the latter of whom are required by force of circumstance to supply medicines from their own houses; but each and all of these departments of the profession must be cared for, must be duly considered, in any legislative measure that will answer the ends for which we believe all legislation is or ought to be undertaken; viz., the protection of the community, and the security of the individual. It obviously will never answer to cut out any Utopian scheme adapted to a state of things having no actual existence. The true business of legislators, as the Duke of Wellington once very wisely said, is, in fact, much less to propose new measures than to adopt those which the common sense of the community led them to believe they required. The enactment, having the medical profession for its object, must necessarily deal with the exigencies of the great mass of its members; it were a mockery to legislate particularly, for fractional portions of the profession, physicians and surgeons, and to leave the integer,—the general practitioner, as much out of the question as if he were not in being.

We also see our way out of our present difficulties by means of the proposed incorporation of general practitioners into a distinct College; and in dim perspective we can even fancy that we see the possible blending, by its means, of the three branches of the medical profession which we now have in England into one harmonious and influential whole.

The grand difficulty we had in contemplating the subject of the incorporation of the general practitioners into a separate College last week was this: that, supposing a charter of incorporation granted, and even a power of

licensing granted—though we saw strong grounds for apprehending a most formidable opposition to the latter proposition,—that the letters testimonial from a body so constituted as the College of General Practitioners of Medicine, Surgery, and Midwifery, would not be received at their fair value either by the public or the profession itself. The policy of the general practitioners at this critical moment would obviously be, as we apprehend it, not only to insist on an independent charter of corporation, but to consideration as a “THIRD ELEMENT” in the medical profession along with the College of Physicians and College of Surgeons. We would not have the general practitioner attempt to sever himself or his College from either or from both of these institutions; he ought to take his stand on his right to consideration as an integral part of the medical profession, and on his title to a share, *but no more than a share*, in the examination of the future general practitioner. The examining body in the new bill was proposed to be constituted of a deputation from the College of Physicians, assisted by the Apothecaries’ Society, and a deputation from the College of Surgeons. Let it be made up of certain numbers deputed from each of the three Royal Colleges, which, together, should constitute the faculty of medicine of England: say *three* from the College of Physicians, *three* from the College of Surgeons, and, to balance these, *six* from the College of General Practitioners. This is but giving the full, instead of the half or quarter, measure of justice which the bill contemplated when it hung the Society of Apothecaries round the neck of the Royal College of Physicians.

The letters testimonial of the general practitioner would then carry the signatures of the presidents of the respective Colleges and Courts of Examiners of each, which would of course com-

prise the men most familiarly known to fame, and of highest eminence in the profession, whether as physicians, surgeons, or general practitioners, by which both the public and the professional man himself would be satisfied.

With this arrangement, the fees paid would of course be divided into *three portions*, instead of being all appropriated by one as heretofore, or by two as contemplated by the new bill; by which each of the three Royal Colleges would thrive, and become powerful; and the interests of every branch of the profession being found to be identical, and frequent contact for a common purpose engendering confidence and respect, is it almost certain that the three Colleges would merge into one GRAND INSTITUTION, animated by a single spirit, though made up of different members, singularly calculated to advance the interests of medical science, and to raise the profession of physic in public estimation.

MEDICAL ETHICS.

THE members of our profession are improving. Even as play-actors and circumforaneous mountebanks make their presence duly known by placards and public advertisements, and sound of trumpet and thump of drum, so do the members of the medical profession begin to let their whereabouts be known by circular letters, and notifications in the newspapers. The following letter has been circulated extensively in Hastings within the last ten days or a fortnight, and as it is a printed and public document, we cannot suppose there is any impropriety in our republishing it, and making it still more notorious. When its author printed it, he of course did not intend that it should remain unrecd; and he will therefore be indebted to us for making it still better known than it is. In delicacy to a juvenile brother, however, we only give the initials.

“C—— B——, M.D., Member of the Royal College of Surgeons of England, Licentiate of the Worshipful Society of Apothecaries, London, Member of the Royal Medical and Hunterian Medical Societies, and of the Obstetrical Department of Queen's College, Edinburgh, and formerly House-Surgeon to the Edinburgh Royal Infirmary, in selecting Hastings as his future residence, for the purpose of practising as a Surgeon, begs to submit to the inspection of the Nobility, Clergy, Gentry, and the public in general, the following testimonials of his professional attainments.”

Whereupon follows a number of testimonials, mostly from Edinburgh teachers, all declaring what a very clever young man Dr. C—— B—— is. The professors (extra-academicals, we think, every one) have much satisfaction, or much pleasure, or great pleasure, in bearing testimony to the talents, zeal, assiduity, and success with which C—— B——, M.D. prosecuted his studies. From these same certificates we learn that C—— B——, M.D., during the term of his pupilage, gained a medal in the surgical class, the first prize in the materia medica class, the prize given annually in the class on the practice of physic, and the first medal in the midwifery class. We farther learn, that the same C—— B——, M.D., during the session 1843-44, wrote his thesis “upon the general nature and treatment of scrofulous disorders,” “which displayed an unusual knowledge of those dangerous maladies;” and by a foot-note to the title of the thesis—the foot-note being evidently added by C—— B——, M.D., for the edification of all whom it may concern—“that consumption is one of the worst forms of scrofula.” The circular winds up with an “N.B. Dr. B—— will give gratuitous advice on any medical or surgical case, to the poor of the town and neighbourhood, between

the hours of 9 and 11 A.M., every Monday and Friday, at his present residence, No. 13, Hill Street."

We make no comment upon this circular: we can but regret that things have come to such a pass with the members of the medical profession, that they are compelled to resort to such means for obtaining notoriety. One thing, however, we do feel called upon to object to, and this is, the parade of gratuitous advice to the poor on Monday and Friday morning. Dr. B—— may certainly settle himself where he pleases, but he has no right to take the bread out of honest men's mouths, by offering that for nothing by which they live.

As we are upon this subject, we may as well notice a circular of another description which appears to have been sent to every medical man in the metropolis whose name appears in the Post Office Directory. It purports to have come, or at all events, it is intended to be addressed to the Editors of the London Medical Directory, care of C. Mitchell, Publisher, Red Lion Court, Fleet Street. These gentlemen appear disposed to anticipate Sir James Graham's scheme for general medical registration; they say, the legal profession has its law list, in which the name of every legally qualified practitioner in the kingdom is enrolled, and also an ample London Law Directory, containing every particular respecting the constitution of the Courts of Law, &c. and the names of persons engaged in the legal profession in the metropolis. The London Medical Directory proposes to itself more than this; it will not only give the name and address of every physician, surgeon, and apothecary, resident in London and its vicinity, but it is also intended to give "brief professional notices comprising the nature and date of his qualification,

diploma, or license, description of practice, general or special; whether connected with any hospital, dispensary, infirmary, learned society, club, or other public institution; titles of his works, and nature of his contributions to medical or general and periodical literature; the discoveries or improvements he may claim; comprehending also any other point of interest appertaining to his professional life." With a view to assisting them in their enterprise, the editors of the London Medical Directory request information on certain particulars, with which we must presume our readers to be as familiar as ourselves, and conclude with the following general request: "Please to add any facts connected with yourself, appertaining to your position in the profession, not comprehended in these queries."

If any of our brethren allow the world to remain in ignorance of any one particular which he himself thinks it of importance they should know, they will plainly have themselves to blame: the editors of the London Medical Directory will commit the information they receive to the steam-press, and it will of course be immediately distributed far and wide.

The idea here may be ingenious, but it is not new. We remember,—what shall we say, something like thirty years ago? a learned gentleman, but very poor, who started the same notion, and hunted it to a successful conclusion. This poor man's name we think was Nesbitt. He waited upon all the members of the medical profession domiciled in London, especially the young ones, to whom he of course made it appear that their very existence was involved in their cutting a favourable figure in the pages of the work he projected, and he requested information by private letter precisely of the same kind as that which is now required by the editors of

the London Medical Directory;—the name at full length; the residence—of course every medical man wishes his residence to be known; his qualification, where obtained, and the date—and in those days there were not so many Giessen, Erlangen, and other medical degrees, that can be obtained without residence and without study, as in the present times;—if the author of any work, and its title; if a contributor to the periodicals; if the inventor or proposer of any medical or other novelty; if possessed of any medical appointment; if the member of any learned society, or of any of the clubs, &c.: and precisely as the editors of the London Medical Directory do in circular, did poor Dr. Nesbitt request that the name of the party he called upon might be added to his list of subscribers to his work. What the sum may be which the editors of the London Medical Directory propose for their publication we know not, but Dr. Nesbitt's, we remember, was one guinea. Dr. Nesbitt's book saw the light in due season, and each worthy member of the Royal College of Physicians and the Royal College of Surgeons, *who had subscribed his guinea*, had the satisfaction of viewing his own portrait drawn from the life by himself.

The business did not end here, however; money—even a very handsome sum—will come to an end: and the exchequer, nndry, must again be supplied. Dr. Nesbitt now began visiting his old supporters,—not to speak to them in the character of supporters of themselves,—and informed them, with distress and alarm in his air, that all his private papers, including the letter from Dr. — or Mr. —, had been seized upon by ruthless creditors, who threatened to publish them as they were, and without any such castrations as he (Dr. Nesbitt) had thought it right to perform upon them, unless they were severally redeemed at handsome sums, varying, of course, with the presumed capabilities of each individual contributor: in one case one guinea, in another case two guineas, in a third three guineas, and in a fourth, and where the writer had “laid it on with a trowel,” and could stand the shot, five guineas—sums at which the respective writers of those letters very generally saw the propriety of redeeming them. By *this ingenious procedare*, Dr. Nesbitt re-

cruited his exhausted finances for a time, and the writers of the several letters alluded to had an opportunity of putting them in the fire.

A Medical Directory we do not object to; but it must be without note or comment.

MOVEMENT IN THE PROFESSION.

THE agitation has not yet come to an end: from the *Somerset County Gazette* of the 7th inst. we find that the members of the Taunton and Somerset branch of the Provincial Medical and Surgical Association, and other gentlemen of the medical profession, met on Wednesday, the 4th, for the purpose of taking into consideration the “Bill.”—Dr. Macmullen in the Chair, at which the usual resolutions were passed. The Editor of the *Somerset County Gazette*, in his leading article of the day on which he reports the proceedings of the meeting, makes the following observations:—

Sir James Graham's Medical Bill.—Our good friends, the Doctors, have this week achieved a double triumph. They have demolished, as far as argument can go, the pet measure of the Home Secretary, and, as a necessary consequence, one of Pattison's best dinners. To be serious, we were not fully aware how extensively the public interests are involved in this measure, which is ostensibly one for the regulation and government of medical practice only. It is a measure which, under the guise of liberalism, hides the worst principles of by-gone ages. It goes to establish a despotism in Government, whilst the presumptuous, though unskilful, and the fraudulent, are invited and encouraged to occupy a prominent position in the commonwealth of physic. The great democratic principle of moulding a popular government by the popular will was argumentatively but boldly assumed by Dr. Burridge, as the only just basis of legislation, and as of peculiar applicability to the medical world.

Our Saxon notions of self-government were somewhat at variance with Sir James Graham's very modest and characteristic proposal to rule the doctors *himself*, with the aid of six Regius Professors, who are, of course, nominated to office by the Crown; six laymen, to be directly nominated by the Crown; and six gentlemen to be elected by the Royal Colleges, subject to a *veto* from the Crown. These very independent coadjutors he proposes to secure by paying them *himself*, in proportion to their services (to whom?) Truly about as corrupt a job as can well be!”

The speeches at this Meeting were able, the spirit excellent, and the proceedings concluded, as the Editor has shown, by about

thirty medical gentlemen dining together at Pattison's Hotel, where, as usual, "an excellent repast was provided."

A large and respectable meeting of the profession was held at Dorchester, on Friday last, in the Board Room of the Dorset County Hospital,—Dr. Jackson, of Dorchester, in the Chair—at which Mr. Spooner, of Blandford, read what has been characterised as a very able analysis of the Bill, accompanied with observations for the information and guidance of those whom time and opportunity had not allowed to make themselves masters of the subject. At this meeting we are pleased to see what we believe to be a better understanding of the projected measure, than we have generally remarked, and we regret that the happy idea of Mr. Spooner has not been more generally acted upon at the meetings that have already taken place. The resolutions did not differ essentially, we think, from those that have generally been adopted. The Editor of the *Dorset County Chronicle* has a good article in the Number of his Paper, in which the proceedings of the Meeting are reported, and sums up with the following paragraph:—

"It will be seen, then, that how useful soever may be some of the details of the bill, it will, if passed, have the effect of discouraging the most important and numerous branch of the profession, at the same time that it will offer encouragement to the practice of the ignorant and impudent pretender."

But the important meeting of all was that which was held on Saturday evening last, at the Hanover Square Rooms, Mr. Pennington in the chair, for the purpose of taking measures for the incorporation of the General Practitioners of England into a distinct College of their own. The Resolutions passed at this Meeting were to the following effect:—

Resolution 1—"That this meeting is decidedly of opinion that prior to the passing of any Bill for the regulation of the practice of medicine and surgery, it is of the utmost importance to the interests of the public, that the general practitioners of medicine, surgery, and midwifery, should be legally recognized and placed in an independent position; and that the executive government be respectfully and earnestly requested to suspend the further consideration of the Bill laid before Parliament at the close of the last session, until this object has been attained."

Resolution 2—"That in furtherance of the object of the former resolution, it is the opinion of this meeting that an association should be immediately formed, under the title of 'The Association of General Practitioners in Medicine, Surgery, and Midwifery.'"

Resolution 3—"That this association use

its best efforts to obtain a complete organization of the general practitioners for the purpose of petitioning for a Charter of Incorporation, to be sanctioned by Act of Parliament, and for taking such other steps as circumstances may from time to time render necessary for the protection of their interests."

Resolution 4—"That the Society of Apothecaries be solicited to co-operate with this association in furtherance of the objects of the former resolutions."

Resolution 5—"That a Provisional Committee of thirty-one members, with power to add to its numbers, and of which not less than seven shall form a quorum, be elected by this meeting, to carry the objects of the association into effect; also to form laws for its constitution and government, to be submitted to a general meeting for its approval."

Resolution 6—"That the Provisional Committee be empowered to form an union with this association, of the different societies of general practitioners in town and country, instituted for similar objects."

Resolution 7—"That upon its formation, one of the first duties of this association shall be to petition the legislature against the re-introduction of Sir James Graham's Bill, and to use every legal means to prevent its passing through Parliament."

Resolution 8—"That the following gentlemen do constitute the Provisional Committee."

Whereupon, in the account which has been kindly sent us, we find a list of all the most distinguished general practitioners domiciled in the north, north-west, and west of the metropolis.

A full report of the speeches made at this meeting having appeared in all the daily newspapers, we feel ourselves relieved of the necessity of making any extracts from them. The Meeting was conducted with the greatest harmony, and with so much tact and system that it is impossible to see the general practitioners of London as otherwise than excellent men of business, well acquainted with the management of affairs that interest themselves, and likely, in the long run, to prove most formidable opponents in any persevering attempt that is made to depreciate or to crush them. "Wherever tyranny becomes exorbitant," as an old and excellent writer has it, "and is not to be curbed by gentle methods, it cancels all the bonds of allegiance: self-preservation, whether natural or politic, being a thing that is indispensably necessary. For would it not be a pleasant thing that one should load another with insufferable insolencies, trusting to this, that the injured person will not defend himself, for fear forsooth of being thought disloyal, though at the same time he has no other remedy for

himself but by being so? For it is undoubtedly a much less fault to be unfaithful to a tyrant, than to establish a succession of tyrants by a tame obedience*.”

REMARKS ON DR. GUY AND HIS REVIEWER.

DR. GUY is instant with us, and seems to insist on our acting as umpire in his case. This we might very well decline; but, urged to the subject, we have thought it fair to take up a couple of the points brought forward by our reviewer, for particular review. We shall take those that stand most prominently forward in the criticism—the *arsenite of copper* and the *sulphuret of lead*,—and having looked rather closely at the construction of Dr. Guy's "Principles," in contrast with that of Mr. Taylor's "Manual," we shall take a few of the points, but always in connection with the one he has touched on in his reply.

1. Dr. Guy considers that he was not fairly treated in respect to the quotation "on habit," which was made from his work. We took this as the first instance that presented itself. There are undoubtedly in Dr. Guy's book stronger instances of plagiarism than this, but we altogether object to the manner in which he treats Mr. Taylor's Manual. He makes extracts, slightly alters the language, intersperses some remarks of his own, and then claims merit for "originality," and fulness of detail. Had he copied Mr. Taylor's Manual verbatim, a charge which we did not make, but on the contrary stated that he had abridged it, there might have been some ground for the line of defence which he has chosen to adopt. It was our business to compare *those parts which resembled each other* in the two works:—the parts which *differed* might have been introduced in order to prevent that resemblance from being easily detected. We express this opinion from having since found that many of the methods of testing poisons, used by Mr. Taylor, and not found in the works of Orfila or Christison, have been taken without acknowledgment by Dr. Guy, and so shifted and transposed, as to make it rather difficult to detect the fact, though it is no less certain on that account. Dr. Guy appears to imagine that it is no offence to use the writings of another author in this way; but to that opinion we cannot assent.

2. With respect to the arsenite of copper, Dr. Guy is under an entire misapprehension. It has been known to all chemists, since the discovery of this compound by Scheele, more than sixty years ago, that arsenious acid might be obtained by heating the arsenite of copper; but, as far as we know, in no work on toxicology

prior to Mr. Taylor's was this given as a simple method of identifying the green precipitate formed in arsenical solutions by the copper test. Some toxicologists have given the original experiment of Scheele under the lead of arsenite of copper, but Mr. Taylor and Dr. Guy give it as a collateral proof, in the use of the *liquid reagents* for arsenic. It is not a little remarkable that Dr. Guy should thus give this experiment exactly in the place, and for the very purpose for which Mr. Taylor gives it, and for which no other toxicologist has hitherto given it.

Dr. Guy says that the serious "oversight" which he committed in stating, that metallic arsenic might be obtained by heating arsenite of copper, proves of how little importance he deems the test. We said nothing about its importance as a test; we adduced it as an instance of Dr. Guy copying Mr. Taylor's Manual, and at the same time entirely misunderstanding the nature of the experiment. These points we think are clearly established by the foregoing remarks.

3. Dr. Guy's account of the equivalent of the sulphuret of lead is a piece of mystification. In no work on toxicology, we believe, prior to Mr. Taylor's were the *quantitative analyses* for poisons given. Dr. Guy has not only imitated Mr. Taylor in this respect, but in most of the poisons he has taken the identical numbers used by Mr. Taylor, simply converting the decimal into a fraction, so as to give an apparent variation. In the quantitative analysis for copper, Dr. Guy gives the proportion of black oxide of copper which corresponds, not to a certain weight of *metal*, but of the *metallic salt*—*i. e.* the sulphate. In the quantitative analysis for lead, however, he gives the weight of sulphuret corresponding to the weight of the *metal*—lead; which has no more to do with the determination of the weights of the salts than if he had merely calculated the sulphur, and not the quantity of sulphuric acid, from a given weight of sulphate of larytes. Why has Dr. Guy made a difference with respect to copper and lead? The answer is, that in this, as in some other cases, he has blindly copied Mr. Taylor without perceiving the true object or intention of quantitative analysis. There is no stronger proof of plagiarism than that deficiencies or errors in a work, are thus indiscriminately copied.

We have Mr. Taylor's authority for asserting that the formula for quantitative analysis given by Dr. Guy at p. 562 of his volume, is one which has been used by him in his public lectures at Guy's Hospital since 1831. It is there given without the least acknowledgment, although Dr. Guy either copied it, or had a good opportunity of copying it, when he was taking his "very short but useful notes" at the "familiar demonstrations on toxicology" given by Mr. Taylor.

* Dr. Geddes, Church History of Ethiopia.

With respect to equivalents generally, the facts are still more strongly against Dr. Guy, and still more clearly shew the system of copying which he has pursued. All chemists agree about the equivalents of *dry acids*, and all equivalents of acids are given in this form only in chemical works, but it is well known that there are great differences of opinion in respect to the quantity of water with which they are combined as *Hydrates*. Sulphuric acid may be either a mono-

or a bihydrate—nitric acid a mono- or sesquihydrate; and with respect to muriatic acid, the differences of opinion respecting the quantity of water combined with it, are still greater. Now what do we find in Dr. Guy's book:—that on these very points, where some originality or difference of opinion might fairly be expected, there is an exact agreement with the Manual. The quantitative analyses in the two works, stand thus:

	Taylor.	Guy.	real result.
Sulphuric Acid (100 gr. Sulph. Bar.) =	41½ gr.	41½	41·52
Nitric Acid (100 gr. Sulph. Potash) =	about 82	about 82	81·8
Muriatic Acid (100 gr. Chlor. Silver) =	69	69	69·44
Oxalic Acid (100 gr. Oxalate Lead) =	42 crd. acid	42 crd. acid	41·9

This table appears to us to furnish irrefragable proof, not only that Dr. Guy has adopted the plan of quantitative analysis from Mr. Taylor's Manual, but that he has actually *appropriated his results*. It is clear to us, that Dr. Guy could not have calculated the numbers for himself, or we should not have found him using integers, dropping decimals, or substituting fractions, exactly where the same course is pursued in the Manual. By the above table he stands convicted; and yet he lost no time in appearing at our tribunal, pleading not guilty, and condemning the charge of plagiarism brought against him by the reviewer as most unfounded and unjust! We might

carry out the proof still farther with respect to other parts of his "Principles," but it would require a reprint of much of the whole book to show the real extent of the plagiarisms of which he has been guilty. We think it right, however, to present the following table of the tests for arsenic, as they are described in the works of Orfila, Christison, Taylor, and Guy. We have taken Dr. Christison's second edition, as being at hand: we have no reason to believe that the tests employed by this excellent toxicologist have been much altered in the last edition of his valuable treatise on poisons. Orfila's fourth edition was published in 1843.

Mode of using the tests and processes for arsenic adopted by

Orfila, 1th Edition.

Arsenious Acid as a Solid.

1. Taste.
2. Heated on copper or iron, volatilized without smell; on red hot charcoal, garlick odour.
3. Reduction test. Heated in a tube with carbon and carbonate of potash.

Tests in solution.

1. Solubility of arsenious acid—acid taste.
2. Precipitated yellow by sulphuretted hydrogen properties of precipitate.

Objection to tests.—Arsenic present in glass—denied.

Marsh's test.

3. Ammonio sulphate cop- } No observa-
- per. } tions or objec-
4. Ammonio nitrate silver } tions stated.

Process for Organic Liquids.

Reinsch's test.

Arsenite of potash. Arsenite copper.

Arsenates.

Sulphurets of arsenic.

Christison, 2d Edition.

Arsenious Acid as a Solid.

1. Taste.
2. Heated sublimes in crystals.
3. Heated with charcoal. Reduction test.
4. Solubility in water.

Tests as a solid.

1. Reduction test charcoal or black flux.
2. Lead stains in glass.
3. Tellurium, cadmium, and potassium, differences of cadmium not particularized.
3. Metallic crust converted to arsenious acid dissolved in water and tested.
4. Garlick odour.
5. Deposit on copper by reduction with charcoal.
6. White powder moistened with ammonio sulphate copper.

Tests in solution.

1. Sulphuretted hydrogen precipitate reduced by flux.

Objections to the test.—Cadmium, tin, and antimony—answers to the objections.

2. Ammonio-nitrate silver.

Objections.—An alkaline phosphate (phosphoric acid not mentioned)—common salt.

3. Ammonio sulphate copper—objections. Bichrom potash.

4. Lime water.

5. Separation by galvanism.

Organic mixtures.

Arsenite of copper. Arsenite of potash.

Arsenate of Potash.

Sulphurets arsenic.

Mode of using the Tests and Processes for Arsenic adopted by

Taylor.

Arsenious acid, solid masses or powder.—
Solubility in water.—Taste.

Powder.

1. Entirely volatilized by heat any residue impurity, sometimes plaster of Paris.
2. Heated in small tube sublimes in crystals.
3. Dissolved by caustic potash, forming arsenite potash.
4. Powder in watch-glass, with hydrosulphuret of ammonia. No change of colour until heated and ammonia expelled; yellow sesquisulphuret of arsenic left.
5. Reduction by carbon, and fluxes: garlick odour.

Objections.

Corrosive sublimate, volatile like arsenic, but turned yellow by potash.

1. Glass black lustre from lead.
2. Charcoal.
3. Arsenic in glass lost by heat.
4. Oxide of cadmium.
5. Mercury in white silver globules.

Solution.

Faint acid reaction.

1. Evaporated on glass plate, well-formed octohedral crystals obtained.
2. Ammonio nit. silver.
3. Ammonio sulph. copper, green precipitate, yields arsenious acid on sublimation, in crystals.

Objections to tests.

To silver test a phosphate and *phosphoric acid* (hitherto, we believe, overlooked).

Organic liquids coloured by the tests.

4. *Gaseous test.*—Sulph. hyd. Hydrospt. amm. gives no precipitate without an acid. Properties of precipitate (see Manual, page 149).

Objections to the test.

Cadmium, tin, and antimony, and answers 149. Substance of these copied by Guy, but the order of objections somewhat changed.

Marsh's test.

Reinsch's test. In this one objection, hitherto, we believe, unnoticed (an alkaline sulphuret), taken by Guy from the Manual.

Processes in organic liquids.

Quantitative analysis.

Arsenic acid, page 159. Order of tests taken by Guy, but apparently purposely inverted.

Sulphurets of arsenic.

Arsenuretted hydrogen.

Guy.

The experiments in Italics are taken from the Manual: we do not find them in Orfila or Christison's work, but they are to be found in the Manual.

Arsenious acid, solid and in powder.

1. Solubility in water.
2. Slight acid reaction.
3. Faint sweet taste.
4. *Solution evaporated — well-formed octohedral crystals.*
5. *Combines with alkalis, forming soluble arsenites.*

Powder.

1. Entire volatility by heat — plaster of Paris may be left.
2. *Add liquor potassæ, no change. Corr. sub. turned yellow.*
3. *Powder in watch-glass, with hydros. ammonia.—No immediate effect. Yellow sulphuret after some hours, or after heating it.*
4. Heated in tube, sublimes in octohedral crystals.
5. Reduction by charcoal and fluxes.

Objections.

1. Charcoal.
2. Mercury.
3. *Oxide cadmium* (copied from Manual almost *ipsisimis verbis*).
3. Lead in glass.
4. Arsenic in glass.

Solution.

1. Sulphuretted hydrogen.
2. Ammon. nit. silver.
3. Ammon. sulph. copper.
4. *Hydrosulphuret ammonia, and acetic acid.*

Objections to liquid tests.

Alkaline phosphate, and *solution of phosphoric acid.*

Objections to Amm. Sulph. Copper.

Among the answers, a ring of *metal* (*not arsenious acid*) obtained on heating the precipitate!

Gaseous test.—Sulph. Hydrogen.

Objections.—Cadmium, tin, and antimony, and answers identical page 457.

Marsh's test.

Reinsch's test.

Processes for organic mixtures.

Quantitative analysis.

Arsenic acid: analysis inverted, but passage identical (see Guy, page 464).

Sulphurets of arsenic.

Arsenites, potash and copper.

4. In no work on toxicology before Mr. Taylor's were there distinct chapters, sections, or paragraphs, on the rules for in-

vestigating cases of poisoning; on the period of time within which poisons prove fatal, including the longest and the shortest known

cases; on the quantity of poison required to destroy life, with the largest and the smallest doses; and, lastly, on the quantitative analysis of poisons. Some few scattered facts relating to these questions were to be found in other works on toxicology, but they are here for the first time classified and arranged, together with all the objections to the tests for poisons, and the requisite chemical answers to the objections. Dr. Guy adopts the same subdivisions, and yet he has the boldness to assert, that the arrangement of his entire part coincides very closely with that adopted by Dr. Christison, and has been "little influenced by his perusal of Mr. Taylor's work." Further, he states that the order in which the several tests are placed is one peculiar to himself, and which he has always followed in his lectures. We have ascertained by inquiry, that Dr. Guy has lectured for five years—that the first and, we believe, only course of practical toxicology which he ever attended, was that to which he was gratuitously admitted by Mr. Taylor in the winter of 1838; and yet he wishes us to believe, that the notes which he then took, and the experiments which he then for the first time saw, form no part of his work! Let any one take the pains to compare his tests with those given by Orfila, Christison, and Taylor, and we do not hesitate to say, that the resemblance to Mr. Taylor's mode of using these tests, will be found much stronger than in the other cases, and the method of testing solid poisons by applying reagents to them, will be found to be almost entirely taken from Mr. Taylor.

One word more with respect to quantitative analysis. Admitting that Dr. Guy, with his five years' experience of chemical toxicology, did more than Orfila or Christison had done before him, *i. e.* attached from his own knowledge of the subject, and without reference to Mr. Taylor's, or any other work, the quantitative analyses of poisons—we still beg our readers' attention to this remarkable coincidence: to whatever poison Mr. Taylor gives a quantitative analysis Dr. Guy does the same, and where Mr. Taylor omits it, as in the case of the alkalies, the iodide of potassium, and other compounds, Dr. Guy also omits it. Thus, Mr. Taylor gives a quantitative analysis for antimony, and not for tin, and Dr. Guy does the same. What inference can be drawn from this, and his copying the defect in the case of the sulphuret of lead, than that he has appropriated the results of Mr. Taylor's labours? We think these facts prove that the "odious accusation" has not been built upon so slender a foundation as Dr. Guy would have us and our readers to believe.

Dr. Guy thinks that it is impossible "to

treat the facts of chemistry as subjects of dispute, or to display originality in chemical equivalents;" and this is his answer to the charge of appropriating the tests and quantitative analyses from the Manual! Chemical toxicology and chemistry are, however, in this respect, widely different. There are very few who employ exactly the same tests for poisons, or if they do, they have some peculiar method of operating with them. There is sufficient room for originality, and if any one doubts this let him draw up a list of the tests actually used, and the mode of using them, by Orfila, Christison, and Taylor; he will then see that, although some well-established tests and processes are common, as they must necessarily be, yet there are many others either new, or modifications of old tests, which are peculiar to each writer. On placing Guy's tests by the side of these, they will be found to assimilate very closely to those of the Manual, and some of them have never yet appeared in any other toxicological treatise. They may, it is true, be founded on well-known chemical principles, as all useful tests must be; but it is the application of them to special purposes that we have to regard; and in this application, Dr. Guy approaches so closely to Mr. Taylor, if we except an occasional transposition of an experiment in the series, by which the order of resemblance is only apparently destroyed,—that we hardly know how to receive Dr. Guy's assertion—"that the order in which the several tests are placed is one *peculiar to myself*, and which I have *always* followed in my lectures."

There is only one additional point which requires notice. In the review, we find it stated that Mr. Taylor was deeply versed in medico-legal lore when Dr. Guy could have been little more than a school-boy—nothing more than a medical student certainly. From inquiries which we have made, we find that this statement, at least the latter part of it, is substantially correct. Mr. Taylor, it seems, began to lecture at Guy's Hospital in March, 1831. Dr. Guy received his first lessons in Toxicology from Mr. Taylor, in the chemical laboratory of Guy's Hospital, in the winter of 1838. Thus Mr. Taylor had been a teacher of the subject seven years before Dr. Guy had even become a pupil, in reference to Medical Jurisprudence and Toxicology. We understand that Mr. Taylor gave him permission, by courtesy, to attend his demonstrations on Toxicology, and that no restrictions were placed upon his performing experiments, making notes of the results, or copying any diagrams, tables, or formulæ, used at the lectures. We are now informed, by Dr. Guy, that these were "*very short notes*," and of no use to him in the composition of his work!

We here close this unpleasant subject. We have said this much to show that our reviewer was justified in the severity of his criticism, and we shall now leave Dr. Guy definitively to the judgment of his professional brethren. We thought of winding up by quoting Dr. Guy's own letter, published in the *Lancet* a few weeks ago, upon this very subject; but we thought it would be strengthening our hands too much.

SURGERY OF THE HOTEL DIEU.

"THEY manage these things better in France!" it is often said, and there are many among us, particularly younger members of the profession, who really think so, and who advocate the system of public concurrence among candidates for hospital appointments, and who maintain that the opportunities for the education of medical men are superior in Paris to what they are in London. "The tree is known," &c. Let our readers accompany us through the details of the following case, and, with us, admire the procedure of a child of the *Concours*, which we will not do our neighbours the injustice to characterise as "French surgery," but which we may still be permitted to call "surgery of a professor of the *Hôtel Dieu*," an establishment which is one of the grand points of attraction with English and American students of their profession.

A young man was admitted into the *Hôtel Dieu* affected with ex-ophthalmia, or protrusion of the left eye from the orbit, very probably occasioned, as the Professor observed, by the presence of a tumor in the bottom of the orbit, which, pushing the eyeball forwards, and compressing the optic nerve, destroyed the sight; for the eye, although to all outward appearance sound, was completely without the faculty of vision. What may be the nature of the infra-orbitary tumor? It is difficult to predict. Perhaps it is not of a malignant kind, and yet it could not be removed without removing the eyeball at the same time. I greatly regret having to sacrifice so important an organ as the eye, the more as it is healthy in appearance; but I do not see how else the ophthalmia is to be remedied. The operation was done, and deftly done; the eye was extirpated to the very root of the optic nerve, and the patient was dressed and sent off to bed. The Professor continued: "Before proceeding to the operation, the idea struck me that it might perhaps be possible to remove the tumor without touching the eye, and so this organ would have been left in its place, if not as an instrument of vision (for I did not believe it possible to restore its powers) yet as an appearance, or as a stump upon which an artificial eye might have been

engrafted. Unquestionably the position of the patient would have been better than that it is now with the orbit empty; but I am disposed to think that the advantages of moment to a person mixing in society, and interested in hiding a deformity, were very trifling in connection with our patient, whose lot was cast in the country. And then the removal of the tumor, sparing the eye, it still being possible, would nevertheless have been attended with great difficulties; so that, all things considered, I have thought it best to proceed as I have done, sacrificing an organ which could no longer suffice for the uses for which it was intended by nature.

"What may be the nature of the tumor which we have now before us, it is difficult to say. From the absence of all severe and lancinating pain, however, we might infer that the tumor was not melanotic; and now that it is divided in two nothing is seen that positively resembles cancer.

The lad died a few days after the operation, with all the symptoms of meningeal and encephalic inflammation. "The important point in the necroscopy was the state of the optic nerve—*Eh bien! on le trouva avec toutes les apparences de l'état normal. Well! it was found with every appearance of health.*"

[Comment upon this case would be waste of words: the procedure was in every respect unjustifiable, barbarous; and the poor lad as certainly lost his life through the inhuman practice of the surgeon, as if he had had his throat cut. There can be very little question but that the simple fleshy, or, from aught we have to the contrary, steatomatous tumor, removed, and the optic nerve long kept on the stretch relieved, it would gradually have recovered its powers, so that the poor fellow would not only have run no risk of his life, but would have recovered freed from his deformity, and with his vision perfect in both eyes. The additional risk to life from so serious an operation as extirpating the eye-ball seems never to have been taken into the cruel surgeon's mind; to extirpate a tumor from the orbit may be, must be, a difficult operation; but it is not necessarily one that brings the life of the patient into jeopardy, which the extirpation of the eye-ball necessarily does.—*Ed. Gaz.*]

LUXATION OF THE HEAD, AND FRACTURE OF THE NECK, OF THE THIGH BONE.

A MAN, 70 years of age, fell from his waggon, and was dragged along the ground for some short distance: found himself incapable of moving afterwards. I found the right thigh in the position indicative of fracture of the

neck : the limb was shortened three inches, it was easily brought down by extension ; rotation was readily performed, and no crepitation in the seat of the joint or the trochanter, which was no longer to be felt ; in the groin, on the contrary, and under the skin and fascia, there was a globular body the size of an apple, and which could be pushed a few lines in every direction ; it was the head of the thigh bone detached from the neck and shaft. A surgeon had already seen the patient before my visit ; had diagnosticated luxation forwards, and with the help of several men and great exertion, had attempted reduction, in the course of which, the patient himself and the bystanders felt and heard a loud crack. It is possible that the thigh had been first luxated and then broken in the neck, but I can scarcely suppose that this was the case, or whence the great difficulty in the attempt to reduce ? and whence the crack without reduction ? An incomplete fracture before the attempt at reduction can scarcely be conceived, but it is very possible that the natural fragility of the bones in a man of 70 years of age, permitted a fracture to take place in the course of the vigorous effort that was made to reduce the luxation. In a youthful subject I should probably have resolved on removing the fragment ; the motive to have done so was sufficient from the amount of disturbance it occasioned by pressing upon the nerves and vessels of the groin ; in present circumstances, however, I contented myself with placing the limb in the easiest position for the patient, and without extension. The numbness and swelling of the limb gradually disappeared in the course of four months, the head of the thigh bone occasioned neither inflammation nor suppuration, and by and by became fixed by adhesions in its new situation. The shortened thigh is not without motion in its new joint, and the old man goes about with the help of crutches.—*Basedow, in Caspar's Wochenschrift*, No. 29, 1844.

DR. HOME.

DR. HOME, long Professor of Materia Medica, and then Professor of the Practice of Physic in the University of Edinburgh, from which he had retired but a few years, died lately at a very advanced age—86, we believe.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

List of Gentlemen admitted Members, Dec. 6.—G. F. D. Evans.—V. Hutchinson.—J. A. Walmsley.—T. H. Watt.—W. H. Meadows.—R. Thornton.—H. Douglas.

APOTHECARIES' HALL.

Gentlemen who have obtained Certificates, Dec. 5.—R. Q. Wallace, Dublin.—Henry

Douglas, Grantham.—J. G. Grylls, Cornwall.—R. W. Sanneman, Hounslow.—Geo. Gardiner, Bristol.—R. Scott.

MORTALITY OF THE METROPOLIS.

Deaths from all causes registered in the week ending Saturday, Nov. 30.

WEEKLY JOURNAL

OF

Medicine and the Collateral Sciences.

FRIDAY, DECEMBER 20, 1844.

LECTURES ON THE NATURE AND TREATMENT OF DEFORMITIES,

*Delivered at the Bloomsbury Square
Institution.*

By R. W. TAMPLIN, F.R.C.S.E.
Surgeon to the Institution.

*Treatment of Genu valgum or knock-knee
by general means, mechanical, and sur-
gical and mechanical—Genu extorsum or
outward inclination of the knees—treat-
ment of ditto.*

We will now consider the treatment, which consists of general, mechanical, and surgical and mechanical means combined. In children, when the deformity is slight, or when there is great mobility of the joint, so that the legs can with slight force be brought into the straight position, and when the general health is, and has been disturbed, from whatever cause, your attention must be directed to the improvement of the general health in the first instance, and to the removal of the causes of such disturbance, if they still exist. You will, as I mentioned to you, find the secretions unhealthy, the appetite bad, the surface soft and flabby, and a generally diminished tone of all the tissues, occasionally—I may say frequently; the abdomen large and tumid, either with or without mesenteric disease. You will then have recourse to those measures of relief which may appear best adapted to each individual. I have found alterative doses of the Hydragryi c. Creta every other night, continued for some time (say two or three grains), according to the age of the child, of great use, with Tincture of the Sesquichloride of Iron, in small doses, administered three times a day, either in water or Infusion of Calumba. I say small doses, for I have frequently seen irritation set up in the mucous membrane of the alimentary canal, from what is generally considered as an ordinary dose. Children in

this state do not bear medicine except in the mildest forms, nor is it necessary, for we are not called upon to treat an active disease, nor do we expect any sudden or immediate change; but rather to assist than supersede nature in her efforts. The form I have ordered is ℥ss. of the Tincture to ℥vj. of fluid, of which they take, at twelve months of age, one tea-spoonful, two or three times daily; if two years of age, two tea-spoonfuls at a dose, and so on in proportion; and in this way all the good effects expected are derived without the risk of gastric irritation. You will find it necessary to pay attention to the diet also, which should consist of milk, eggs, meat, and plain food. These unfortunate children are dosed with, what is called, "tea," which means warm water, night and morning, with bread and butter, which is far from sufficient nourishment; occasionally I recommend small quantities of beer; by these means the improvement is generally rapid, if properly followed up by the parent or attendants of the child. If, then, the deformity is to any extent beyond what we should call incipient, you will derive much benefit from the use of the straight wooden splint, either applied by strapping it to the limb through its entire length, or with straps and bandages, as we use at this charity. If, however, the deformity is to any extent, you will find the splint I have adopted and used with great comfort to the patient and satisfaction to myself, the best mechanical means, either with or without an operation (Fig. 1). In the most severe deformity in a child under five years of age, you may cure it in this way, provided you proceed cautiously, and keep the limb in its proper position, well adapted to the splint, which admits of being applied in any position in which the limb may be, from the most simple to the most severe case.

I have used with advantage a splint made of two zinc plates, the one portion to correspond with the thigh, the other with the leg, as in the splint represented, but instead of a screw, a straight piece of iron or wood attached by a hinge to the centre of each of

the portions of the splint on the outside. The zinc, from being soft, admits of being applied close to the limb, and can be fixed by means of strapping in the position in which the joint is; a webbing strap passed round the knee and over the connecting piece of iron, will by gradually tightening it, effectually straighten the limb. In some I have also added a joint in the centre of the iron to correspond with the knee-joint, so as to allow of flexion and extension, but I prefer the knees being kept extended.

FIG. 1.

Diagram of the splint, which consists, as may be observed, of two portions, the one for the thigh, the other for the leg, and united by means of a hinge, fixed on the outside of the splints. Straps are alternately placed throughout the entire length, so that the leg is retained in position both to the posterior and lateral surfaces. By means of the male and female screw at the outer side, it can be applied at any angle, and extension can be gradually kept up.

Of course the division of the tendon will expedite the treatment, but not, I think, sufficiently to warrant its being done at this early period. At a later period, however, when the tendon is very tense, I would advise its section, which you will do in the following manner. Let the patient lie on his

side, and let the assistant place one hand under the lower portion of the inner side of the thigh, so that the leg rests as it were on his hand, and with the other hand grasping the leg, let him endeavour to straighten it. In this way the tendon will be rendered more tense, and may be readily felt as it passes on the outside of the joint. You then introduce a small sharp-pointed knife under it, turn the sharp edge towards the tendon, and divide it; or you may adopt this plan, which is sometimes preferable: direct the patient to flex the leg, and direct the assistant offer some resistance, in this way the tendon is raised, as it were, from the joint, when by passing the knife under it, the assistant at the same time forcibly straightening the leg; then on turning the sharp edge towards the tendon you will find it is divided most easily; but you must be careful the knife does not pass through the skin, as by the suddenness with which it is done there is some risk of this occurring.

You may occasionally divide the peroneal nerve; I have done so in two instances; paralysis of the flexors of the foot was the result in both cases, which continued from four to eight, or ten weeks, but the power gradually returned, and no evil result followed. If you pass your knife carefully under and close to the tendon, not beyond it, you will not divide the nerve, except it is lying upon the tendon: it is as well to use every precaution to avoid this, as the paralysis occasions a good deal of doubt and uneasiness to the patient, or friends, which you will find the greatest difficulty in allaying, as they will tell you they fear the loss of the use of the foot, which in fact is for a time actually the case. You then place a piece of lint and strapping over the point of puncture, and support the lint with a bandage, either with or without a splint; I prefer in all cases the use of the splint, as it serves to keep the joint motionless, and adds much to the comfort of the patient. In the course of three or four days you will generally find the puncture healed; you then apply the splint, and proceed with the extension, more or less rapidly, according to the severity of the case, the rigidity met with, and the pain experienced by the patient; for I need not tell you, that the restoration of the limb to its natural position, after years of its being kept in the malposition, is always attended with pain; the pain, however, should never be allowed to interfere with the appetite, or rest of the patient: this you may regard as a guide in the treatment. I am now speaking, recollect, of the pain in the joint itself, not that which may be occasioned by undue pressure, which last ought to be immediately relieved; you must at all times be careful that the pressure is uniform throughout the entire extremity, as you may be inconvenienced, and have the treatment retarded, by a slow and

open wound. After the limb is restored to its perfectly straight or natural position, you will order upright supports from the hips downwards, and keep the knee-joint in the straight position during the time exercise is taken; the leg may be flexed and extended at other times. These supports must be continued night and day, until the patient is enabled to stand and walk without the joints yielding, and must not be omitted before, as a relapse will certainly be the consequence, independently of prolonging the treatment. In slight cases, in the adult or youth, irons alone, the knees being kept straight, perfect the cure of this deformity, and in a short time, compared with the more severe. In children, when merely incipient, the use of the rocking-horse, with attention to the general health, will supersede the necessity of mechanical treatment, as there is a constant effort made in riding to cling to the horse, and adduct the legs; hence the bowed condition of the legs of those accustomed from early life to horse exercise. It is of no use to attempt to straighten the legs solely with irons, if the deformity exists to any extent, as the legs will rotate in them, and the thigh and leg become everted, which disguises, but does not relieve, the deformity. Numerous cases of the kind have presented themselves at this Institution. Irons are only of use in severe cases, after the legs are straightened, in maintaining the position, by assisting the joints to bear the superincumbent weight of the body during the time they are incapable of doing so unaided, and allowing exercise to be taken whilst the ligaments are gaining strength, which exercise improves the general health and strength of the patients, and enables them to follow their usual occupations without risk of relapse. It is a common thing to find females with a slight deformity of this kind, or a tendency to it, which I attribute to the great width of the pelvis, compared to that of the male, and which causes the thighs to be separated from each other to such an extent at the upper part, that the articular extremities of the lower ends or condyles are necessarily placed in an increased oblique position, the internal condyle projecting: this alteration in the pelvic extremities is, as you are aware, the only change that takes place (in my opinion) when the deformity arises without debility, or when the articular surfaces of the femur are in their actual proper contact in every direction with the articular surface of the head of the tibia.

I must now draw your attention to another deformity of the knee, namely, outward inclination, or genu extorsum (see fig. 2.); this is also a very common affection in children, whose constitution is naturally unhealthy, and who are rachitic, and is invariably combined with curvature of the tibia and fibula, which I regard as the immediate cause; the patient appears to be bow-legged, when it af-

fects both legs. You will occasionally, but rarely, find it in one extremity, and combined, as you are aware, with knock-knee in the fellow-limb. It does not appear to arise from any alteration in the relative position of the articular surfaces of the tibia or femur, or from any change in the healthy condition of the ligaments attached, at least not permanently, but occurs in this way. If the tibia is curved outwardly in one sweep, commencing just above the internal malleolus, the head of the bone is of course thrown more outwardly than is natural; the femur being held firmly by the connecting ligaments, and being freely moveable in the hip-joint, as a matter of course follows the direction of the tibia; then the legs diverge from each other in one uninterrupted curved line from the hips to the ankles, and if you grasp the thigh firmly, and then attempt to straighten the limb, you will find by doing so, which you generally can to a greater or less extent, that an interspace can be felt between the internal condyle of the femur, and the internal articular surface of the head of the tibia, showing that in their curved position the articular surfaces still remain in actual contact, and that the deformity does not consist in a relaxed condition of the ligaments, but in the articular surface being thrown out of its natural horizontal position. Outward inclination will occasionally be met with to a great extent, the knees being several inches apart, whilst the internal malleoli are in actual contact; it is combined in these severe cases with talipes valgus, as in knock-knee, only with this difference, that in knock-knee the articular cavity of the ankle-joint is in an oblique lateral direction, the outer side being raised and higher than the inner, while in outward inclination of the knee you have just the reverse, namely, the inner side is raised, the outer depressed; in the one case, the stretching and elongation of the internal lateral ligaments arises principally from the pressure occasioned by the weight of the body; in the other, it occurs from the raised portion of the internal malleolus, combined with the weight of the body; or if the astragalus keeps its relative position in the articular cavity, the patient will be thrown on the outer edge of the foot; but as the outer edge is the first portion which touches the ground in these cases, when the weight of the body is thrown upon it, it is forced upwards until the whole of the sole of the foot touches the ground, and this can only take place by the elongation of the internal lateral ligament: you will perceive what I mean by referring to the cast before you. This deformity arises during the early period of childhood; I have never seen it occur at a later period, nor can it, if my opinion be true that the curvature in the bone is the primary cause, as this softened condition of the osseous system is as a rule confined to

FIG. 2.

Cast of a patient 26 years of age, in which may be observed the general curve of the tibia, commencing immediately above the internal malleolus, and the raised condition of the internal malleolus, as described.

childhood; the bones becoming hardened as the child increases in age, and the general health improves, after the irritation of teething, and the eruptive diseases have ceased to exist, provided the osseous disease is not constitutional. Of course you have the rachitic condition in patients who have arrived, or nearly so, at adult age, but these affections differ from those in which the bones merely yield, for in these latter, not only a yielding, but a brittleness of the bones generally exists, which admits of fracture from slight causes, as in the *fragilitas osseum* met with in old people; patients thus affected walk in a very unsteady manner, with what is called "a whaddle," rolling from one side to the other, and do not possess that free motion which is natural in the normal position of the knee-joint. It is true the knee is flexed and extended, but not to its full ex-

tent; the patient losing power in proportion to the deviation from the straight line; it is a hideous deformity, giving the patient an appearance of diminished size and stature, and it is instantly recognised by every individual. The treatment is general and mechanical; in children affected with this deformity, you will find very generally that unhealthy state of constitution I have already described, existing with those affected with the last mentioned deformity; this must, of course, be attended to by administering alteratives and tonics, with attention to the diet. The mechanical means we adopt consist of straight splints on the inner side of the leg, extending high up above the knee, and below the internal malleolus, well padded at the points of pressure, and webbing straps applied round the leg and splint, so that a constant steady pressure may be kept

up : it is only by the most gradual and uninterrupted treatment that good can be obtained, for you must recollect that not only the knees, but the bones also, are affected, and a child cannot bear any amount of continued pressure ; it must be so applied that the child is subjected to no pain. This rule must be invariably your guide ; you can in this way in young subjects overcome the deformity, and if the splints are carefully applied, the little patient can walk with greater comfort and firmness with them than without them. Irons have been and are daily used ; I object to them, because you cannot keep up such uninterrupted support as you can with a webbing strap and splint, and without this, of course, all treatment is useless. It will occupy many months, which it is as well to inform the patients, or friends, as they will become impatient and dissatisfied. With regard to those who have been thus afflicted for years, when the bones are consolidated, it is a question if you should try or advise any treatment ; you must recollect the articular surfaces are not in fault ; therefore, if you straighten the leg at the expense of the articular surfaces, you cannot expect the patient to be enabled to manage without a support. We have had one patient in the Charity, above twenty-six years of age, who was determined to have something done, and who submitted with the prospect of wearing irons for life ; in this case I divided the semi-membranous and tendinous tendons, and straightened the legs about half, by means of the splint, which I adopt in knock-knee ; the splint being applied on the inner side of the leg. A great improvement in his appearance is the result, but not such as would have induced me to have submitted to the treatment, or advise its being done in similar cases.

ON FRACTURES OF THE FEMUR.

By W. LYON, Esq.

Lecturer on Surgery, and lately one of the Surgeons of the Glasgow Royal Infirmary.

[Continued from p. 346.]

(For the Medical Gazette.)

CASE IV.—*Fracture of cervix femoris, or trochanter—inversion of foot—mistake in diagnosis.*

J. M. æt. 71, Oct. 4, 1841.—This old man fell from a stair, and alighted on a pump ; but whether he received the shock over the point of injury is not stated.

It is noted in the journal, that he complained of pain at hip-joint, where there was considerable swelling and rigidity of muscles, with a prominence resembling the trochanter major, to be

felt on the dorsum ilii. The limb was shortened two inches : crepitation could not be detected by *extension and rotation*, and the toes were *inverted*.

The case had been supposed one of dislocation, and an attempt had been made, by the aid of the pulleys, to effect reduction.

At the visit next day the symptoms were unchanged, but considerable latitude of motion, capability of restoring the normal length of the limb by extension, and its immediate shortening, convinced us that fracture, and not dislocation, existed. The advanced age of the patient forbade retentive measures, and the limb being placed in the easiest position, fomentations were applied. Considerable pain and constitutional disturbance followed, which soon subsided, and he left the hospital in December, with the limb shortened and *everted*, but its functions rapidly returning. The inversion, and the absence of crepitation, were the only symptoms which could mislead in this case, and the capability of making considerable *abduction*, the extent of *general motion*, the restoration of the *healthy length* by extension, completely contra-indicated the conditions denoted by the two first symptoms, and should have prevented the erroneous diagnosis arrived at.

The extent of shortening, two inches, rendered it likely the fracture was external to the capsule, and that, therefore, union without shortening might be effected. Had the patient been young, middle aged, or slightly beyond the latter, an attempt to procure union without shortening would have been perfectly safe, and very probably successful. It is not so, however, in the aged, as I have oftener than once seen exemplified. This danger is generally acknowledged, but in several cases I have witnessed the pain after an accident of this kind to be so severe, and to be inducing and keeping up such an amount of excitement, as to incite to the application of the usual apparatus, with the view of keeping the injured and highly excited parts at rest. From this the worst effects arise : the patient is kept constantly resting on the same parts, and from the diminished power of the nervous and sanguineous systems consequent on old age, sloughing, or ulceration of the soft parts exposed to pressure—the nates and sacrum—are almost sure to occur. Constant pain,

restlessness, and irritation, are thus induced; the deepening and extending of the sores bring on hectic, with profuse perspiration and diarrhœa, and these, added to the disturbance occasioned by the local effects of the injury, soon prove fatal. It may be insisted, that the patient is not only as well able, but is better able, to shift his position with, than without the apparatus. Feasible as this may appear, it is not the case, and besides, he is much longer confined, not only to the bed, but to one position, when he has, than when he has not, the apparatus applied, and of course, ulceration, or sloughing, are in proportion more apt to be occasioned. Nor is retention by apparatus of so much importance as at first sight it may be supposed. When the fracture is partly within and partly without the capsule, or in the cervix external to the capsule, or through the trochanter major, osseous union is of course usually attainable in the young or middle aged.

In the aged, however, supposing it always possible to determine the exact seat of the fracture, the attempt to procure union, even in fractures external to the capsule, is replete with danger, and making it is the more reprehensible, that ossific union can be safely obtained without it, the only difference being, that the limb will be shorter than its fellow and somewhat weak; conditions, however, much to be regretted, the avoidance of which is not to be sought for, at the peril of life.

I am aware that the attempt to procure ossific union by the use of the common apparatus, in fractures apparently external to the capsule in those advanced in life, is advocated by high authorities*; but taught as I am, by experience, of its danger, I would not now, in patients above sixty, especially of weakly habit, emaciated, and to be treated in an hospital, upon any account undertake the serious responsibility. In more than one instance I have tried the practice; ulceration or sloughing have always supervened, the patients have died, and I have found the fractures extending through the trochanter. Better far, in truth our imperative duty, to place the limb, as was done in the subject whose case originated the present remarks, in

an easy, and as far as possible normal position, obviate pressing symptoms, permit such motion as the feelings of the patient demand; allow him to rise when able, and trust to the agglutination of the surrounding tissues, the apposition and union of the often broad surfaces of the fracture, a *safe* attempt to cure, and in general, a very serviceable, though abbreviated limb.

It may be urged that this was not a case of fracture through trochanter, or neck external to the capsule, and that union was not effected, the cure being accomplished by formation of a false joint, or rather by the absorption and rounding off of the surfaces at the fractured part, the weight of the body being sustained mainly on the capsule. The most careful examination after the cure convinced me that the fracture had occurred at the trochanter, and that osseous union existed.

The most positive sign of fracture—crepitation, was wanting in the subject of our remarks, and in my experience in similar cases I have frequently found it so.

When the shortening is so considerable that the one fractured surface is drawn past the other, of course crepitation cannot be elicited; but even when by extension they are brought opposite each other, and moved, this sound or feeling is not always observed, as the case detailed exemplified.

For this, various reasons may be given. When there has not been displacement, crepitation may be prevented by the unlacerated investments not permitting sufficient motion; or, it may likewise be prevented by much irregularity of the fractured surfaces, spiculæ from the one, projecting and locking into roughnesses or depressions in the other. From the latter state I have seen it impracticable to produce crepitation in fracture of the tibia, or to restore the proper direction of the foot, and much deformity and eversion thereby result. Or again, the surfaces may have broken smoothly, and crepitation be prevented by copious sanguineous extravasation: or a portion of muscle may slip in and keep separate the surfaces. We see, therefore, that the absence of crepitation does not indicate the absence of fracture; and recollecting that crepitation from thick or viscid secretions into or around an articulation is not unusual, neither

* Liston's Practical Surgery, p. 76.

is the presence of crepitation to be taken as an undoubted symptom that the bone has given way. It follows from this, and from the fact that the investments are sometimes unlacerated, and do not permit displacement, that there may be no shortening, no crepitation, no eversion, and yet the cervix or trochanter be fractured. We know, too, that when the hip-joint has been simply bruised, to prevent the pain arising from motion, or involuntarily from the effects of the injury, the surrounding muscles contract, and the head of the femur is drawn and kept up to the superior part of the acetabulum, causing the limb to appear shorter, thus simulating fracture; and, if conjoined with synovial crepitation, being peculiarly apt to mislead. We thus perceive that it may be difficult, if not impossible, always to distinguish bruise from fracture; and likewise that rude examination may convert a fracture without displacement into one with shortening of the member.

Not only, then, may there be fracture while there is no crepitation, and little or no shortening, but, as our case proves, the injury may exist while another symptom, *eversion*, is likewise wanting, and not only wanting, but the contrary condition—inversion, one of the symptoms of dislocation—may be present.

The fact of the occurrence of inversion being known, I am not sure that any practical advantage may be gained by attempting to account for the mode of its production, the more especially that it will be impossible to ascertain which of the various causes on which it is asserted to depend is present in any given case. I must, however, qualify this opinion by stating that as it is desirable to rectify the position of the foot if inverted, so are its causes important to be known, that we may be able safely to attempt its removal.

I believe that some of its causes have been demonstrated by inspection of the injured parts: others are only inferred from supposition or analogy. The state of the bone, the direction of the fracture, the shape of the fragments, the conditions of the investments, the action of particular muscles, the direction of the inflicting force, have been shewn or surmised.

We can suppose that the one fragment may be driven in, or locked in

another, so as to maintain inversion; that the investments intact anteriorly hold the fragments in contact, while being lacerated posteriorly, they permit separation and turning in of the foot; that the fracture running obliquely inwards and backwards, the rotators acting upon the internal extremity of the fragment, no longer fixed, will draw it backwards, and of course turn the toe in the opposite direction; that the same muscles, the external rotators, may, by pricking of the fragments, be excited to increased action, and, acting on the shaft unattached to the cervix, will likewise turn the toe inwards; or, that, independent of any of those conditions, on producing some of them, the violence inflicting the injury may be so applied as to turn the trochanter forwards, and consequently the great toe inwards. In whatever way the inversion be accounted for, we believe, as we found to happen, that it will, by the weight of the limb, or the restored balance of muscular action, generally merge into the opposite condition of eversion, with which state of foot our patient was discharged.

Nevertheless, of the absence of crepitation and of shortening, if inversion existed after an injury of the hip-joint, seeing that it occasionally exists in fracture, and not in any other kind of injury, with exception of several species of dislocation, in which there is always shortening, we would, if it were present in those circumstances, have tolerably strong reasons to believe that it depended on fracture.

There is a symptom of fracture not yet mentioned, the comparative segment of a circle in which the trochanter of the injured side rotates, which can always be observed when shortening is present, and occasionally when it is absent: we have almost always been able to detect a marked difference between the rotation of the trochanter on the injured and opposite sides, a difference not only showing the non-existence of dislocation, in which the trochanter cannot be made to revolve, but in many cases unequivocally establishing, even although the general signs are absent, that fracture has been suffered; to decide, however, by this sign on the exact point of the cervix, reckoning the trochanter as part of it, in which the fracture is

situated, cannot, we fear, be done with a very close approximation to exactitude.

With all the difficulties arising from the absence of one or more of the usual symptoms, or the presence of any of those contra-indicating, it is seldom they are all combined in one case; and it must be rare indeed, where there is any displacement, that the skilful and careful practitioner cannot distinguish the easily, though painfully, moved, the abbreviated, but readily extended, limb, and rotated fractured cervix or trochanter, from the dislocated member—rigid, confined in its motions, and incapable of rotation or extension but with the employment of much force.

The diagnosis of severe bruise from fracture without displacement is difficult in all, is impracticable in many cases. The possibility of converting, by rude examination, fracture without displacement into fracture with displacement, should be kept in recollection: and as shortening, though absent at first, sometimes shows itself after a few days, a case dubious one day may be evident enough soon after; points which may give rise to disagreeable difference of opinion between one practitioner and another, and between the surgeon and his patient.

Not only does the female less often suffer from fracture of the femur than the male, we having only had six in the former, while we had thirty-five in the latter, but our cases strongly show the well known-fact, that when fracture of the femur does occur in the female, it is generally in the cervix or trochanter, for out of our six examples in the female there were five of the trochanter or cervix; while in thirty-five males there were only two with the fractures at those parts.

There was reason to believe that all of them were external to the capsule; two of them were, by dissection, shown to be through the trochanter major. With one exception, the patients were above sixty years old. In three of these, retentive means were used: one died from an old diarrhoea, aggravated by sloughing; another from constitutional irritation and sloughing; and in a third the retentive means were interrupted on account of incipient sloughing. In one under fifty, union without shortening was effected

by the usual apparatus; and in another of sixty-five, the limb was supported in an easy position by pillows, and fomentations applied. She was allowed to shift when inclined, and in a few weeks left the hospital with the fracture united, and with the limb, though shortened, rapidly gaining strength: thus corroborating, when contrasted with some of the other cases, the propriety of not employing retentive means in patients of advanced age, even though the fracture be evidently external to the capsule, the more especially as without them ossification and a useful limb can be quickly and safely obtained.

CASE V. — Fracture of shaft of femur — sloughing — death. Post-mortem appearances.

June 30th, 1842. W. M.K. æt. 77. Five days ago fell out of bed, and fractured femur at junction of middle with upper third, where soft parts are swollen and tense. Patient has paralysis agitans, is very feeble, and has irregularity of pulse.

The limb was treated by Desault's plan, modified as formerly described: general health of patient was attended to; he was allowed generous diet, and, after a short while, four ounces of whiskey daily.

The skin over sacrum soon began to give way, and by Aug. 9th, at which time motion at seat of fracture was still perceptible, and in opposition to stimulants of various kinds, and the constant use of air or hair pillows, the sore had become four inches in diameter, and exposed the bone. The health now became much disturbed, the appetite failed, exhaustion rapidly advanced, and he died on the 11th of August, about six weeks after admission.

The soft tissues around fracture were found thickened, infiltrated, vascular, and with a few osseous particles interspersed. This was the only medium by which the fragments of the unusually thick and brittle femur were united.

No internal morbid appearances were discovered.

The symptoms, and the absence of any morbid appearance, excepting the large bad sore, entitle us to conclude that this patient died from the irritation

and exhaustion occasioned by the large, painful, ulcerating surface; and the constant confinement in one position necessitated by the splint and bandage, having been the cause of the ulcer, it becomes important to decide whether, in weak persons of advanced age, it is advisable, in fractures of the shaft of the femur, to follow the ordinary treatment for that injury.

It must be allowed that this patient was rather an unfavourable specimen of a person at the age 77; and it may be urged that it is unreasonable to draw a general rule from a single case, and that one, too, of a more unfavourable kind than most of those of a similar description.

With the exceptions mentioned, the patient looked healthy on admission, and took his substantial fare and allowance of whiskey with relish; and, seeing how trying are the effects of long-continued confinement to bed, apart from disease, on the young and robust, the diminished capability of resistance of the old and frail, the observance of the effects of pressure at advanced periods of life in fractures near the hip-joint, and the fatal result in this instance, I certainly, in a like example, would either adopt different treatment from the commencement, or more carefully watch, and, if requisite, interrupt the kind of procedure which I employed.

There is even a risk from the temporary use of the ordinary treatment; for if it has been used so long as to induce sloughing, the confinement will likewise have much debilitated the patient, and from the effects of these, and the pain in the injured part from motion, it will be found difficult afterwards, if not impracticable, to enable him to take exercise, or to make and support any change of position from that of reclinaton on the back, which the body will invariably assume from the influence of gravity, and therefore the sloughing will extend, though the splints, &c. have been removed. For these reasons it is desirable, if not essential, that from the commencement the treatment shall be such as will allow frequent change in the position of the body, while immobility in the seat of fracture is maintained. It will not be easy to combine these requisites in a perfectly effectual manner, nor in such way as to preserve

the length and contour of the limb, especially if the fracture be oblique; but activity and power are not to be expected in the very old and infirm, in whom only I advocate a departure from the ordinary treatment in fracture of the shaft of the femur; and, however valuable activity and power are, they ought to yield to considerations involving the safety of life, which, I feel assured, will be frequently sacrificed by adherence to the usual procedure.

It is improbable that the patient will be able, in a case of this kind, to rise in a few days after the injury, as in fracture within the capsule, where, besides, the object wished is formation of a new joint, while in this it is especially sought to be avoided. Nor will there be the same likelihood of ossific union here if the patient be made to rise early, without means to prevent motion, as there is in fracture through the trochanter major, where the fractured surfaces are broad and often rough. Though apparatus of any kind be dispensed with, we doubt if a very old and infirm patient with fracture of the shaft would resist the exhausting effects of confinement to bed, shift his position as often as to prevent bed-sores, and that at same time union would occur.

With the ordinary apparatus, the patient cannot move sufficiently while in bed; and out of it all attempts at taking exercise are debarred.

We want a method possessing immobility and lightness, and the only plan by which these are attainable is in the employment of the leathern splint and starched bandage, as applied in morbus coxarius. And were I again to meet with a fractured femur in a person on the verge of 80, I would fit a piece of undressed leather, of length sufficient to extend from a little above pelvis to the feet, broad enough to cover a third of the hip and limb, and of shape corresponding to the member when slightly flexed. This being softened by water, I would cover with a thin layer of carded cotton, or two or three pieces of cotton cloth, and secure with gentle firmness to the body and limb by starched bandage. Being dried, it would form a firm, tight mould for the limb, and I would permit and urge the patient to change of position in the bed, to rise from it as early as possible,

and take exercise with the aid of crutches.

In this manner his health would be preserved, sloughing be prevented, and union likely ensured.

There might be deformity, or even non-union, but even the latter is a slight evil when compared to the risks of confinement, which, in such circumstances, should never, in my opinion, be encountered.

A CASE OF TUBERCULOUS EXCAVATION OF THE LEFT LUNG,

TREATED BY PERFORATION OF THE CAVITY
THROUGH THE WALLS OF THE CHEST.

By JOHN HASTINGS, M.D.

And ROBERT STORKS, Esq., Surgeon.

(*For the Medical Gazette.*)

E. G., a clerk, ætat. 38, remarkably intelligent, of a nervous sanguineous temperament, and born of healthy parents. Had always enjoyed good health until the last four years, when he suffered from a nervous fever, accompanied by an affection of the heart, from which he was many months recovering. Whilst in Ireland in the summer of 1841, he was attacked with severe cough, hæmoptysis, and expectoration, which he believed originated in cold; great debility ensued, and although the cough and expectoration diminished, he never regained his strength. In the spring of last year hoarseness, loss of voice, cough, expectoration, and extreme weakness came on, apparently through severe cold; this was shortly followed by an attack of typhus, which confined him to bed for nine weeks. On recovering from the fever, the cough and expectoration had increased, and from the debility which followed, he was compelled to take to bed for the winter. On the 10th of February, Mr. Whidborne, a surgeon in Queen Square, was called in, who put the patient under a course of the naphtha treatment; from which he benefitted so much, that in six weeks he was able to take exercise out of doors. By the advice of some of his friends, he became an inmate of the Hospital for Consumption at Chelsea; but as he did not improve, after a sojourn of three weeks he returned to his home.

On the 10th of August, by the advice of Mr. Whidborne, he consulted me. His cough was troublesome, and often occasioned pain in different parts of the chest. His expectoration, streaked with blood, and of a puriform character, amounted from two ounces to half a pint daily; dyspnœa was considerable, appetite tolerable, and bowels regular. Expansion was deficient over the left clavicular region, where percussion yielded a dull sound. An extensive blowing murmur, with here and there a gurgling râle, and pectoriloquy, were well-marked. Over the same region, on the right side, the vocal resonance amounted to bronchophony; the respiratory murmur was more or less bronchial; the sound on percussion, although it had not the clearness emitted by a healthy lung, was not very dull, and expansion was natural. His pulse were 132, respirations, 32; height, 5 ft. 6½ in.; weight, 7 st. 8½ lb.; and he expelled 122 cubic inches of air from his lungs, by a forcible expiration, as shewn by Hutchinson's breathmeter. The naphtha treatment was ordered to be continued, with generous diet. From this time he continued slowly to improve, up to the beginning of November, with the exception that he was thrown back by five attacks of inter-current pleurisy, when blisters and a lowering treatment were had recourse to, and the naphtha and nourishing diet suspended. His pulse were 108; his weight had augmented to 7 st. 11 lb. The physical condition of the right lung had undergone improvement, but the cavity in the left had decidedly increased. As I saw no prospect of closing the cavity by medical treatment, and consequently no hope of his becoming much better than he then was, I determined to propose the operation of making an incision into the cavern through the walls of the chest, to which he at once assented. I had previously explained that it was not an experiment, for Dr. Barry,* of Dublin, had more than a century ago recommended a somewhat similar operation; and at a subsequent period, in a work on Indigestion,† he published several cases where its use had been attended with complete suc-

* E. Barry, M.D. A Treatise on a Consumption of the Lungs. Dublin, 1726. Pp. 217.

† E. Barry, M.D. A Treatise on Three different Digestions, &c. London, 1763. Pp. 366.

cess. Its disuse has probably been owing to the want of the stethoscope; for without auscultation, the existence and situation of a cavity in the lung cannot be satisfactorily demonstrated. We find Dr. Barry directing the operator to the situation of the cavern, by the seat of previous pain, by augmented temperature over the space it occupies, and by the *elevation* of the ribs. With such limited knowledge, nay inaccurate data, it is surprising that any surgeon could be persuaded to perform the operation. It will not be difficult to believe that serious and fatal errors occurred in consequence, which soon put an end to the operation, which may possibly turn out to be one of the most important we are at present acquainted with. Dr. Barry has reported a case which terminated fatally, where the surgeon had not reached the cavity by an inch and a half. In this instance pleurisy and effusion probably caused the death of the patient; but now, with the aid of the stethoscope, no such disastrous results are likely to occur. I may here observe, that for a considerable period I had come to the conclusion, that the great difficulty of curing phthisis in its latter stage, arises not so much from any obstacle that the nature of the disease offers to the healing process, as to the distension and contraction which the sides of the cavity continually undergo from respiration. The idea of overcoming the difficulty by an operation, such as has been employed in the following case, did not occur to me until I met with the invaluable facts and observations of Dr. Barry. To my mind they confirmed, in a great degree, the views just stated, and I determined the first opportunity to attempt the arrest of the disease by this method. The primary object Dr. Barry had in view was the discharge of the fluid within the cavity; the removal of the cause of the secretion was my aim. No one can doubt that these cavities owe their origin, in the first instance, to the ripening of tubercles; but their persistence and augmentation result, I believe, as before stated, from the distending and irritating effects of the air within the cavity. Hence the object was to remove this, which appeared to me might be effectually done, were a tube of sufficient calibre passed into the cavity, that would admit the escape of air as

fast as it entered; so that a state of repose being secured, the walls of the cavity would be in a much more favourable condition for uniting. It is reported that an operation of this nature has been lately performed in Germany; and Dr. Hocken* observes, "I may remark, that the operation recently proposed, of making a free external communication through the walls of the chest with a phthisical cavity of large size, replete with morbid secretions, is (if it could be effected safely) likely to render the case more curable, provided the extent of disease present, and the predisposition of the patient, allow the smallest shadow of hope to remain."

Nov. 15th.—Having previously consulted my friends, Drs. Hocken, Burslem, and Mr. Storks, on the case, the latter undertook the operation; and we accordingly proceeded to the patient's house for that purpose at half-past one. He was in good spirits; the cough was troublesome; the puriform expectoration amounted to three ounces, which had been discharged during the morning; the pulse were 120. After carefully auscultating the left clavicular region, it appeared to me that the walls of the cavern were thinnest between the third and fourth ribs, about an inch and a half from the sternum, where Mr. Storks decided on making the opening. The operation is detailed by Mr. Storks at the conclusion of my history of the case. Shortly after the opening was made into the excavation through the walls of the chest, the pulse sank to 100, and the cough, expectoration, and dyspnœa ceased. A little faintness occurred during the operation, which was removed by a few tea-spoonfuls of brandy and water. The blowing murmur and pectoriloquy had undergone a diminution in intensity. Quiet, and antiphlogistic regimen, were enjoined. At 7 P.M. the air was passing out of the wound freely. He complained of pain between its orifice and the shoulder, with numbness of the left arm. The pulse were 96; he had neither cough, expectoration, nor difficulty of breathing. He had been a little faint, which yielded to a small quantity of brandy and water. A composing draught was

* A Practical Inquiry into the Value of Medicinal Naphtha in Tubercular Phthisis, By E. O. Hocken, M.D. Higley, 1844. Pp. 60.

ordered in the event of restlessness during the night.

16th, 7 A.M.—As he had been uneasy in the early part of the night, the draught was administered, which procured six hours' refreshing sleep; he was free from cough, dyspnœa, and pain; the pulse 68. He had brought up several times a little frothy mucus mixed with blood; a little bloody discharge oozed from the wound, which looked healthy.

9 P.M.—The pulse were 80. The orifice of the wound appeared to be closed, as no air could be detected passing in or out; notwithstanding which he was free from cough, expectation, and dyspnœa.

17th, 8 A.M.—He had passed a good night, and towards the morning had felt a little difficulty of breathing, followed by slight cough; the discharge being bloody frothy sputa. As the mouth of the wound seemed still closed, a little lint was pushed through the slight adhesions into the cavity.

5 P.M.—He had a slight fit of coughing at three o'clock, which ended in a little expectoration of frothy bloody mucus; the pulse 88. The lint was removed by Mr. Storks, and a piece of elastic gum tube inserted into the cavity.

18th, 8 A.M.—Last evening he took an aperient, which had operated in the early part of the night; and as he was restless afterwards, he took a composing draught, which procured him an excellent night; he had neither cough, expectoration, nor difficulty of breathing; the pulse were 80. He was ordered half a pint of beef-tea twice a-day.

19th, 8 A.M.—He had a slight fit of coughing in the night; no expectoration; the pulse 76; the respirations 24. As no air could be detected passing in or out of the tube, Mr. Storks restored the connection between the orifice of the wound and the superior part of the cavity. He was ordered mutton chop and a glass of ale for his dinner.

9 P.M.—The pulse were 76; he was entirely free from cough and expectation; a little brown-coloured discharge flowed out of the tube. He had taken ten minims of Nap. Rect. in a table spoonful of distilled water, which was ordered to be repeated twice a-day.

20th, 8 A.M.—He had had seven hours of undisturbed sleep. He was

free from cough, difficulty of breathing, and pain. On waking he had expectorated a little frothy mucus. A feather exhibited very distinct movements on being placed at the mouth of the tube. The pulse were 72; the respirations 22. The bowels were confined.

9 P.M.—About twenty minutes after he had partaken of his chop and ale, which he had eaten with an excellent appetite, the whole surface of the body was chilled; rigors succeeded, followed by fever, vomiting, and great pain in the head. The skin was hot and dry; there was great thirst, with spasmodic twitches in the wound; the pulse were 112, but the pectoral symptoms had undergone no change. The aperient ordered in the morning had not been taken until seven o'clock in the evening, and had not acted. It was ordered to be repeated should the first fail to relieve the bowels by midnight. A table-spoonful of the following mixture was also ordered every four hours:—

℞ Creosot. gtt. xxi. ; Aq. Destill. ℥vj. M. fiat misturæ.

21st, 8 A.M.—The bowels had acted twice with the aid of the second aperient, the sickness had ceased, and the pain in the head and heat of skin had diminished. The pulse were 96. He was free from cough, expectation, and dyspnœa.

9 P.M.—The pulse were 88, and the symptoms of gastric disturbance were rapidly disappearing.

22d, 8 A.M.—The pulse were 68; the respirations 24. He had neither cough, expectation, nor difficulty of breathing. A little boiled mutton was ordered for his dinner.

23d, 8 A.M.—The pulse were 74. In the early part of the night the tube had become displaced, and touched the opposite side of the cavity, which produced a sickening heavy pain. On being restored to its former situation, he slept the remainder of the night comfortably, and was free from all pectoral disturbance. He was ordered to recommence the naphtha mixture, and take a little sherry and water with his dinner.

24th, 8 A.M.—The pulse were 76. He had coughed a little upon waking in the morning, and had expectorated about half a table-spoonful of frothy mucus, mixed with a little purulent discharge. He attributed the cough to

his head having slipped off the pillow during the night.

9 P.M.—He had about half-past one, after a long nap with his head very low, a severe attack of cough and difficulty of breathing, with great pain in and around the wound. As Dr. Hocken lived much nearer the residence of the invalid than myself, and had very kindly promised to supply my place in the event of emergency, he was immediately sent for. On arriving he withdrew the tube, which was followed by the escape of about a tea-spoonful of healthy-looking pus; this afforded great relief to the dyspnœa. The irritating cough had been nearly subdued by an anodyne, and expectorating mixture, prescribed by Dr. Hocken, which was ordered to be continued. Whilst the cough continued, frothy sputa to the amount of an ounce was expectorated. The headache was severe; the pulse 100. The naphtha mixture and wine were withheld, and his head and chest maintained in a raised position. Cold lotions were ordered to the head.

25th, 8 A.M.—The pulse were 88; the respirations 28. He had passed a tolerable night, with slight cough, and trifling expectoration of frothy mucus.

26th, 8 A.M.—The cough and expectoration had diminished. He had slept at intervals during the night. The pulse were 100.

9 P.M.—He was generally more comfortable than in the morning; he attributed this to his being able to keep an erect position by the aid of one of Daw's patent chairs. The pulse were 112; skin hot; tongue moist.

27th, 8 A.M.—The pulse were 96. He was very languid; had passed a tolerable night, with slight cough, and expectoration of a brown tenacious mucus, blended with sputa of a purulent character. The appetite was deficient, and he complained of pain in and around the wound. The tube was removed, as it was suspected it might be the cause of the pain.

4 P.M.—The cough was troublesome, accompanied with difficulty of breathing and great languor; the pulse were 100; the skin hot; with a total loss of appetite.

28th, 8 A.M.—The pulse were 84; the cough and expectoration were less; the purulent character of the latter had almost disappeared; the bowels were open. Ten minims of Nap. Rect. were

added to each dose of the mixture, and wine, beef-tea, and animal jelly, were directed to be given.

29th, 8 A.M.—The pulse were 92; the respirations 28; the tongue clean, and the skin moist. He complained of headache, which he had suffered from more or less since the 24th, nausea, and occasional shooting pains. He had had snatches of sleep during the night, his spirits were good, and he felt stronger than he did the day before; the expectoration, which amounted to about an ounce, was chiefly of a mucous character, and of a brown flesh colour. He had taken nourishment two or three times during the night.

[For the report of the condition of the patient during the next two days, and also Dec. the 3d and 4th, I am indebted to my friend Dr. Hocken, in consequence of my unavoidable absence from town, to whom both Mr. Storks and myself feel highly indebted for his kind assistance, and entire concurrence in the treatment which has been adopted in this case.]

30th, 9 P.M.—Appearance much improved; feels much better and stronger; is quite free from headache, except from exertion, or from moving suddenly. Chest and wound comfortable, and free from pain; pulse stronger than in the morning, 92—soft; respirations 24. Has had little difficulty of breathing or cough all day, and did not expectorate anything till one o'clock P.M. Since then has spat up about half an ounce of a transparent, tenacious, frothy mucus, mixed with saliva; some few sputa, very slightly streaked with scarlet blood. Has eaten some animal food (rabbit), &c. with appetite. No fever.

Dec. 1st.—Had passed on the whole a good night; sleep having been several times disturbed by dreams, and pain in the back of the head. On first waking suffered much from headache; but it has gradually decreased, and is at present trifling. Had no expectoration till about two o'clock A.M., since which he has spit up about one ounce of tenacious rusty-looking mucus; some sputa streaked with florid blood. The tongue clean and moist. Bowels moved; stool liquid, healthy coloured. No undue heat of skin: pulse 74; respirations 26. The tube has given no uneasiness, and air escapes with a whist-

ling noise from coughing. His appetite for food has returned.

2 P.M.—Has felt comfortable since morning, and completely lost headache; pulse 80. Wound healing rapidly; tube adherent, bringing away a portion of granulations (evidently from the cavity) between the openings of the tube. Air freely escapes through the wound and tube on the slightest cough or effort. There has been little or no cough, difficulty of breathing, nor expectoration, since the morning. Two or three mucous sputa, transparent, and mixed with air-bubbles, being all that was coughed up. Evening.—Very comfortable; good appetite; pulse 82; has had no expectoration, and little cough.

2d, half-past 8 A.M.—Has passed an exceedingly comfortable and tranquil night (the best night he has passed for some time), and has been perfectly free from headache, or pain in any part. Had no expectoration till about two o'clock A.M., since which he has spit up about half an ounce of a tenacious mucus, without much cough or effort. The sputa are nearly free from air-bubbles, rusty-coloured, some almost of a fleshy aspect, and one with a streak of florid blood. His countenance is expressive of strength, and is quite free from anxiety; lips moist. Air freely escapes through the tube on coughing, or even on retaining the breath, with a hissing noise. He was at breakfast, and eating with appetite, sitting up with apparent ease in the chair. He states that his pulse were about 70 till he commenced his meal; they are now 90; respirations 28.

9 P.M.—The expression of the patient's countenance is highly favourable; and he states that he is conscious of an acquisition of health and strength. During the day he has been perfectly free from headache and uneasiness, and has partaken of food with a good appetite. There has been but little cough, and no difficulty of breathing, except when the sputa were about to be expectorated. The expectorated matters amount to about half an ounce, and consist chiefly of transparent frothy mucus, mixed with some more tenacious sputa, of a brownish colour. Air continues to escape freely through the tube on every effort. The skin is soft, moist, and of a comfortable temperature; lips moist; no thirst. Pulse 80; respirations 24.

3d, 8 A.M.—The pulse were 88; the respirations 20. Air had passed freely out at the orifice of the wound at every inspiration; he was very comfortable; had slept eight hours without cough, and had very little expectoration; the appetite was much improved; the bowels confined. He felt satisfied he was gaining both flesh and strength. An enema was ordered.

8 P.M.—Has passed a very comfortable day, and is conscious of an increase of strength. Thinks that instead of any increase of emaciation (which was the case for the first fortnight after the operation,) he has visibly gained flesh during the last few days. His appetite and digestion are now excellent, and he has been free from any pain or uneasiness. During the day there has been but little cough, and no difficulty of breathing, except when mucus was about to be expectorated. Sputa amount to about half an ounce, chiefly of clear, transparent, mucus, mixed with a few of greater consistence, of a salmon tint. Pulse rather small, moderately strong, and 88; respirations 20. Wound healing most favourably; air passes very freely through the tube. Tube adherent; when withdrawn, removed a long portion of granulations from the cavity. Bowels have not been moved; tongue clean and moist. To use an enema of water gruel, with chloride of sodium.

4th, 8 A.M.—Has passed a very good night, having had about seven hours of refreshing nearly undisturbed sleep. Bowels moved spontaneously, without the use of the injection; stool healthy. Has had but very trifling cough during the night, and has expectorated rather more than half an ounce of a tenacious mucus (the chief part having a fleshy aspect), without difficulty. Air freely escapes from the wound, Pulse 92; respirations 20.

5th, 8 A.M.—He has had an excellent night, without cough or expectoration. On waking had a little uneasiness about the wound, which apparently arose from the tube becoming blocked up with secretion, thereby preventing the free passage of air through the orifice. He had on waking expectorated two or three pieces of tenacious flesh-coloured mucus, similar to that which had been brought up during the last eight days. He complained of nausea after taking his medicine, in conse-

quence of which the *Liq. Op. Sed.*, *Vin. Ipecac.*, and *Mucil. Acac.* were removed from the mixture. He felt stronger; the pulse were 80, and the respirations 16.

6th, 8 A.M.—The pulse were 88; the respirations 16. He had slept well throughout the night, his appetite was excellent, his bowels were open, the cough was very slight, and the expectoration for the last twenty-four hours amounted to not more than a teaspoonful, and was of a semitransparent mucous character.

7th, 8 A.M.—He had passed a good night; the cough was slight; he had discharged about half a table-spoonful of mucus, blended with a few sputa of a flesh colour. His appetite was excellent; his pulse were 90; and the respirations 16. Air continued to pass freely through the tube.

8th, 8 A.M.—He had passed the night in bed for the first time since he had used Daw's chair. Towards morning he complained of cold, and cold perspirations, with great irritation in the stomach and bowels; the latter had been disturbed twice with unhealthy evacuations. He had a troublesome hacking cough, without expectoration, and headache; the pulse 88; the respirations 28. During the night there was a free discharge of thin pus from the wound, through which the air passed freely. He attributed this unfavourable change to a beef-steak he had eaten the previous day for his dinner.

3 P.M.—The following powder was ordered to be taken immediately, and his usual aperient two hours afterwards:—

R Hyd. cum Cretâ, gr. iij.; Pulv. Ipecac.
Co. gr. v. M.

9th, 8 A.M.—The abdominal disturbance subsided after the aperient had acted. He had passed a tolerable night in Daw's chair, which he preferred to the bed. The irritating cough had considerably abated; the pulse 92; the respirations 20.

10th, 8 A.M.—He had had an excellent night, with very little cough or expectoration; the pulse 88; the respirations 18; the appetite good. He was cheerful, and felt stronger. The depressions about the left clavicular region appeared less marked than they

had been. The physical signs about the cavity had undergone no particular change since the last examination. The respiratory murmur in the inferior portions of the left lung was in some places healthy, and in others bronchial, without any marked vocal resonance.

11th, 8 A.M.—He was steadily improving; the pulse were 90; the respirations were 18.

12th, 8 A.M.—He was daily growing stronger. He had no cough during the night. The pulse 80; the respirations 16 to 18. The bowels were confined. An aperient was ordered.

13th, 8 A.M.—He was remarkably well and cheerful; he had no cough during the night, and very little in the day. The pulse 80; the respirations 24. The depressions about the left clavicular region had become more evident.

14th, 8 A.M.—He had passed eight hours of undisturbed sleep. The expectoration for several days past had been chiefly of a mucous character, with an occasional sputum of a brown colour; the whole did not exceed a half drachm to a drachm in the twenty-four hours,—certainly less than many persons expectorate in health.

15th, 3 P.M.—Has had a most comfortable night; pulse 88; respirations 16. Bowels not relieved to-day; has expectorated a very small quantity of transparent mucus, with one brownish sputum; appetite excellent. Has been walking about the room.

The operation performed upon E. G., the individual whose case is recorded above, will not perhaps be thought devoid of interest; and although the proceeding is simple and easy of performance, still those who have had no experience in the operation or its effects, and who may be induced by the perusal of this case to test its advantages, will not consider even the minute details of such a proceeding unimportant.

As it is quite unnecessary, after the report my friend Dr. Hastings has drawn up of the case, for me to make any observations upon the facts that induced us to try the effect of making a communication between the walls of the chest and a tuberculous cavity, I shall at once proceed to detail the steps

of the operation, making such remarks as they may require, but at the same time confining myself strictly to those questions likely to affect the surgical treatment of this fatal disease.

On Friday, Nov. 15, 1844, in the presence of Drs. Hastings, Hocken, Burslem, and Messrs. Whidborne, Douglas, Bayliss, Ion, Coward, and Bowes, E. G. was laid in the recumbent position. An incision, two inches in length, being made at right angles with the left clavicle, in a line with the nipple, which, if prolonged, would have divided it (the nipple) in the centre, the fibres of the pectoralis major were exposed, and divided to a similar extent. The third intercostal space being thus laid bare, a fine hydrocele trocar was thrust into the cavity; and having ascertained to my own satisfaction that air issued from the canula, a scalpel was pushed through the intercostal muscles, nearly in the centre of the space, and carried obliquely upwards into the cavern. A probe being passed along its blade, it was withdrawn, and I was thus enabled to ascertain most satisfactorily that I had penetrated the excavation, the walls of which, as I divided it to the extent of an inch with a probe-pointed bistoury, I found to be extremely dense—indeed, almost cartilaginous. The direction of the second incision was in a line with the ribs, being nearly at right angles with the first incision, there being sufficient space, in consequence of the retraction of the cut fibres of the pectoralis major, for me to make this second incision without again interfering with the integuments. Air and blood immediately escaped from the aperture; and on again introducing the probe, I was unable to move it with the same freedom as when introduced at the small puncture previously referred to. At this moment the patient was seized with a fit of coughing, and brought up two or three drachms of blood, which had escaped into the cavity.

I now endeavoured to introduce a silver tube, made under my directions by Mr. Weiss, which not answering the purpose well, I removed; and as the air was escaping freely, I had him carried to bed, and warm water dressing applied around the wound. On the third day after the operation, a piece of elastic gum catheter was introduced, which has been worn ever since, and

found to answer the purpose better than any other kind of tube.

As it is more particularly my province to describe the best mode of proceeding, as far as my limited experience goes, to effect our object, I do not hesitate to say, from the knowledge I on that occasion obtained, and from the method I have since pursued in the case of a lady to whom I was called by Dr. Hastings, that the proceeding described above was unnecessarily painful and tedious. I may as well here briefly describe what I believe, from the experience of my last case, to be the best method of performing this operation. It being decided in which intercostal space the opening is to be made, an incision nearly two inches long should be made with a narrow straight bistoury along the upper border of the inferior rib of that space down to the intercostal muscles; the instrument should at once be cautiously pushed into the cavity, the consequences carefully observed; and should nothing forbid, the incision should be prolonged to the extent of an inch and more.

Should there be any hæmorrhage from any vessel external to the chest, it can readily be commanded by a ligature applied before the excavation is opened. Should there be any oozing from the cut wall of the cavern, the tube will, by its pressure, I believe, as far as my experience goes, command it. In the case of the lady on whom I have recently operated, there was some oozing, which was readily subdued by the tube and the application of cold.

The reasons that induced me to adopt the form of incision described in the first case was, that had I made the incision in the direction of the fibres of the pectoralis major, I feared much annoyance might be produced by the action or spasm of that muscle. I therefore determined to paralyse that portion of the muscle implicated in the operation by the transverse division of its fibres. That this may be of service in stout muscular subjects I do not doubt, but the surgeon will rarely be called upon to perform this operation when the muscular system is in that condition. The simple proceeding adopted in the last case will, in the majority of instances, be found quite sufficient, occupying as it does a few seconds only; it is, as far as the pain of an ope-

ration is concerned, not calculated to cause more suffering than the infliction of a wound necessary to evacuate the contents of a small abscess. After the incision is made, a piece of a full-sized elastic gum catheter is to be introduced along the wound into the cavern, and retained in its position by a piece of ligature tied round the end (which should project a quarter of an inch beyond the external wound), and the ligatures should be secured by strapping. An ivory cap, similar to the accompanying

engraving, should be applied on the mouth of the tube, with a piece of warm sponge placed in its interior; this serves a double object, warming the air that enters through the aperture, and absorbing any discharge issuing from the wound. This, of course, should be frequently changed, and the cap may be easily secured by a strip of oiled silk passing through the little bands at the side, the ends of which may be fastened to the adjoining integument by a piece of plaster.

The most important point to ascertain, if possible, before such an operation is determined on, is whether the pleuræ costalis and pulmonalis adhere; this, in almost all the cases to which this operation is applicable, will be found to be the case; Louis, on this point, going so far as to say, "If there were no adhesions, neither were there large or medium-sized excavations; generally speaking, indeed, there were none of any kind."—Walsh, Translation, p. 36. All will agree, who have had any experience upon this subject, in the truth of this observation; at the same time, the surgeon cannot divest his mind of the possibility of his opening the pleura, and thus creating pneumothorax. It would undoubtedly, therefore, in relation to this operation, be most important for us to be able accurately to diagnose the presence of adhesions; and it has struck me that the presence of that expansion during

inspiration, and corresponding depression during expiration of the intercostal space over a tuberculous cavity, which is often seen, cannot take place without adhesion of the pleural surfaces. It requires further experience, of course, to determine this point, but I think the suggestion worthy of consideration. Although this operation is not of recent date, it is revived under very different circumstances. The invaluable assistance to be derived from the stethoscope in affections of the lung was unknown to Dr. Barry; we cannot, therefore, be surprised at finding an operation calculated to give, to say the least of it, great relief, falling into disuse, when the surgeon had nothing to guide him to the seat of the disease but pain and increase of temperature.

The further details of this case will be given in a future number.

MEDICAL GAZETTE.

Friday, December 20, 1844.

"Licet omnibus, licet etiam mihi, dignitatem
Artis Medicæ tueri; potestas modo veniendi in
publicum sit, dicendi periculum non recuso."

CICERO.

THE DILEMMA, AND REMEDY THE THIRD.

THE PRACTITIONER OF MEDICINE LICENSED
BY A GOVERNMENT BOARD, INDEPENDENT
OF UNIVERSITIES, ROYAL COLLEGES
OF PHYSICIANS AND SURGEONS, AND
APOTHECARIES' HALLS.

THE point of highest moment to the community in any legislative enactment touching the medical profession, is unquestionably the QUALIFICATION OF THE MEMBER OF THAT PROFESSION. How the Colleges or Corporations with which the profession is associated are to be administered, matters little to the world at large: whether all, or only a few, are to have a voice in the administration of their affairs, or in the choice of the officers and council by which these affairs are administered—whether there is to be one grade or several grades, &c.—all this is of secondary moment. The competency of the men who are

entrusted with the public health is the paramount consideration; and the question then resolves itself into very simple elements: shall the public, and the Government of the country as guardians of the public, be content with moderate competency, with men having a minimum of education; or shall they insist on such competency in the medical advisers of the community as the most careful education, preliminary and special, can alone bestow? Surely there is but one way in which this question, or these questions, can be answered. The community are interested in an infinitely greater degree in a respectable and competent body of medical advisers, than in any other class of functionaries whatsoever. The medical man is now the head and front of every measure having the social welfare and progress for its object. Under his eye disease has long been on the decrease, and it is certain that the causes of disease and early death which are readily remediable are still as legion in comparison with those that have been abated or removed. They will be overcome,—they can *only* be overcome through the ceaseless intercession of enlightened medical men with governors and persons of rank and influence in the commonwealth, who are in general utterly ignorant of the state and requirements of the poor. The medical man and the good priest are the only two members of the educated classes who ever meet in the abodes of sickness, wretchedness, and poverty, and who are in any way competent to advise with a true and not a mock executive upon the means of removing the huge amount of physical and then of moralevil under which the poorer classes lie whelmed.

The *spiritual*, the *moral*, Government has already taken under its special protection through the means of its amply endowed church; shall not government feel it equally a duty to take the *phy-*

sical under its especial protection? And if so,—and we apprehend there can be but one answer to this query,—how is it to discharge itself of this important duty most efficiently? By taking measures to secure to the community a body of highly educated medical men, and by trusting their examination as to competency with no private and irresponsible board; but by assuming the duty of examining members of the medical profession into its own hands, through a public and responsible board, composed of men who by common consent are themselves competent to the difficult office of examiners; who would at all times act under the general eye, and who would have no interest save to discharge their duty faithfully to the community.

We do seriously believe that the government of a country in these times is as imperatively required to provide a succession of fully qualified medical men for the service of the public, as it is to secure impartial judges for the due administration of the laws. The plan by which we think this important object would be best attained is abundantly simple. We would have a board of examiners, independent of all Colleges and Corporations, specially appointed by the Secretary of State for the Home Department, for the purpose of testing the competency of candidates for the license to practise medicine, and to pass this board, to obtain the government license, should be imperative upon all who aspired to the responsible position of practitioner of medicine.

There is in fact but one medical profession, though it be split into several arbitrary subdivisions: the physician, surgeon, and accoucheur, all study the same structure, the same functions in their healthy and disordered states; and they strive, by the same means, to acquire familiarity with the agencies that influence the body in health and disease. The department which each man chooses

in after life is the result of predilection, very frequently of accident, or of circumstance. Let him be left free to select this, and to join a Royal College of Physicians, or a Royal College of Surgeons, or a Royal College of Apothecaries, as he lists, afterwards. Let him go for honours to an University, and acquire a title if he pleases—Government would interfere with nothing of all this. It would only say, as guardians of the public health: "We require every person who proposes to practise medicine in *any* of its departments to have gone through the course of study prescribed by our official Board of Examination, our Council of Health and Education. With existing universities, colleges, and corporations, we do not interfere; our Board or Council prescribes no rules or terms to them; they have full liberty to exact as much more or as much less than our Council or Board require as they please."

We do not think it necessary to enter upon the details of this plan. We would only say this much: that the Board should be tripartite or tri-une—one section being set apart for each division of the kingdom, and holding its sessions at regular and fixed periods—once a quarter, or once a month, in London, Dublin, and Edinburgh.

The Colleges of Physicians, Surgeons, and General Practitioners (should they become incorporated) would then be mere private associations, which government licentiates would join or not as they saw fit; but being associated with which should give no public claim to consideration.

THE PRIME OBSTACLE TO THE SUPPRESSION OF QUACKERY.

WHEN a provincial paper comes into our hands now, we always instinctively turn,—of course, after having read the account of proceedings at the medical meeting which it contains,—to the advertising columns, for the catalogue of quack medicines and quack publications. The following is from a single

number of a liberal newspaper—we dare not add its name, lest the editor should be down upon us for dishonesty, and a dozen other of the deadly sins, as has happened before; but we may say that, save so much space as is occupied by one of Captain J. Rhodes Pidding's medium advertisements of the "Genuine Howqua's Mixture," Sir James's *friends* occupy three columns of the newspaper. The list is the following:—Blackburn's Currant Cough Elixir; Holloway's Ointment and Pills; Wray's Family Medicines, viz., Aromatic Spice Plasters for the Chest, Cough Pills, Essence of Jamaica Ginger, justly celebrated Balsamic Pills, Alterative Tonic Powders and Pills, and Specific Mixture; Ford's Pectoral Balsam of Horehound; Dixon's Specific or Anti-Rheumatic Compound; A New and Practical Work on Premature Decay, enclosed with Dr. Jacques' Eradicative Botanical Pills; Dr. Jacques' Cordial Balsam of Circassia; The 21st Thousand: "Manhood," &c.; Parr's Life Pills; Mr. Thomas's Succedaneum; The 9th Edition: "Manly Vigour," &c.; The 13th Edition: "The Silent Friend;" the Cordial Balm of Syriacum, and Perry's Purifying Specific Pills. We miss Snooks and Cockle, and several other familiar friends, in the above list; but it is long enough notwithstanding their absence.

MOVEMENT IN THE PROFESSION.

THE only meeting of which we have notice—we by no means say that it is the only meeting that has taken place since our last—was held at Sunderland on the 11th inst., Dr. Brown in the chair. The resolutions were of the usual character,—satisfaction with the introduction of a bill into parliament for the regulation of the medical profession; approval of the institution of a Council of Health, but not with its constitution unmixed with general practitioners, &c.; regret at the removal of all restraint from unqualified practice; the necessity of making the projected registration imperative, and the following novelty, as we rather think it, but obvious consequence of what has recently transpired in the metropolis:—"That this meeting views with great satisfaction the plan suggested of incorporating the general practitioners into a college by royal

charter, whereby their interests would be protected, and the representation in the Council of Health and Medical Education, so much desired, might be accomplished." Upon which

"Mr. Mordey rose, and at some length argued that as there were already so many charters, an additional one for the general practitioner would be of no use at all. He thought that in the course of a few short years there would only be two classes of the medical profession—physicians and surgeons; and they ought to bring it to that as soon as possible." We say amen to Mr. Mordey's, in our opinion, very sensible remark. This is what has happened in other countries; wherefore should it not speedily be brought to pass in England?

LONDON MEDICAL DIRECTORY.

We have had information given to us that this projected publication is in the hands of respectable medical men, and that there is nothing quackish or improper in the idea. We have even had a specimen page submitted for our inspection, and not only can find no fault with the execution, but feel disposed to view the thing as likely to be useful. All notorious quacks, all who have fallen away from their high destinies as medical men, though ten times members of the Royal College of Surgeons, should of course be excluded from a list of the profession.

THE GENERAL PRACTITIONERS.

[We have the following from an esteemed friend and occasional contributor. It ought probably to have gone into small type; but our friend having taken the editorial tone, and our printer having set it up large, we give it place next ourself, as containing the views of an influential section of the medical profession."—ED. GAZ.]

LITTLE doubt appears to be now entertained by many influential members of the profession, that the General Practitioners will obtain the object they have set their hearts upon—namely, a charter of incorporation, and a distinct college of their own. The numerical strength and professional importance of the subdivision of the profession to which they belong would of themselves entitle any opinions expressed collectively by this body to great weight and

consideration, even if the cause they advocated had less of truth and justice in it than it really possesses; but when, in addition, we take into account the right-mindedness and business-like notions that characterise all their proceedings, and regard the sound judgment and cogent arguments with which they advocate their cause—and that, too, on public apart from professional considerations—we must in candour acknowledge that we now see no better method of rescuing the profession from its dilemma than by freely conceding to the general practitioners the charter and college they demand.

The chief difficulty in reconciling ourselves to the subdivision of the medical profession into *three* classes of practitioners arose from an anxious desire to retain connected with one or other of our existing Colleges the most numerous and extensively employed of either section, and from a great fear that the majority of the profession would still be degraded by the badge of trade in continuing their connection with the Society of Apothecaries, of the impropriety of which association, our views and opinions have been frequently expressed. But the intelligent general practitioners of the metropolis, as well as generally throughout the country, repudiate such an alliance, and have boldly led the van, themselves taking the initiative: yet, with generous and grateful recollection of their foster-mother—their *pia* mater of the Hall—they invite her to unite with them, dutifully promising to provide her in her extremity with a resting-place and a home. We therefore hope, in sober earnestness, that the general practitioners may succeed in their present endeavours, and that through their means the practice of medicine in this country may be readjusted, by the constitution of a distinct and independent college for each of the three subdivisions into which the requirements of society have arranged the medical profession. We at the same time fervently repeat our former aspirations that there be but one profession, though consisting of *three* instead of *two* classes of practitioners; the new College of General Practitioners being constituted as independent of the existing Colleges as they are of each other.

This plan unquestionably presents the fewest difficulties, for were the

Fellowship of the College of Surgeons thrown open to all its existing Members, that College never could become the head of the body of general practitioners, having no authority to confer a diploma to practise medicine; a privilege which they could never hope to obtain under existing circumstances; and a forced and unwilling connection with the College of Physicians would be equally disadvantageous to both parties.

It is quite clear, indeed, especially as far as the community is concerned, that the general practitioner must be left to his own guidance and direction. Doubtless he will educate himself to as high a standard as the requirements of this great community demand; and if he is contented with the rank and reputation which a diploma from his own college would confer on him, surely the other colleges have nothing to say in the matter.

And now comes the question of pecuniary arrangement—the *main question* after all. But here, too, we think we perceive a method by which all difficulties may be solved, if the arrangements to be made are only entered upon in a kind and liberal spirit: and what a blessing would be conferred upon the community, could these arrangements be undertaken with the anxious desire to reconcile existing differences, and once more reunite our noble profession into a firm, cordial, and zealous body of scientific benefactors to the human race!

We propose, then, *first*, that a sum, to be named hereafter, be appropriated out of the fees paid upon the registration of all legally recognized medical practitioners (such fee and registration to be compulsory, and paid annually), to be paid over to the Royal College of Surgeons, as the guardians and keepers of the Hunterian Museum and Library, and which should henceforth, and in consideration of such annual grant, be open alike to all the members of the medical profession. A registration fee, a portion of which should be appropriated for such a purpose, and as an equitable compensation to the College of Surgeons for parting with its share in the examination fees of the general practitioner, would be a tax that the profession would cheerfully and willingly incur to secure in its integrity that noble collection; the remaining portion of the fees paid on

registration being employed in any way that would conduce to the protection of the community and the security of the individual. Pecuniary matters being, therefore, the difficulty, and the chief difficulty, in any new arrangement of the Licensing Boards of the future members of the profession, we now earnestly and seriously ask the leading members of the great subdivisions of the profession, if private conference and fair arbitration would not be far more likely to lead to an equitable solution of the dilemma, than any public demonstration, however ably or temperately conducted.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Tuesday, December 10th, 1844,

MR. STANLEY, President, in the Chair.

Observations on Cleft Palate, and on Staphylopharynx. By WM. FERGUSSON, Esq., Professor of Surgery in King's College, London.

THE author commences his paper by making some general remarks on the operation for cleft palate, performed in this country and abroad. He then proceeds to give a detailed account of a dissection which he had the opportunity of making of the muscles which operate upon the soft palate, in an individual who had both the velum, and a portion of the hard palate, cleft. This description is followed by an examination of the opinions of different eminent physiologists concerning the motions of the velum palati, and its arches, during the acts of deglutition; and by the author stating his own views as to the actions of the various muscles when the palate is cleft. This part of the subject he further illustrates by describing four different states in which the flaps on each side may be seen upon looking into the mouth of a person who has split palates, and irritating them in different ways. By pursuing this course of anatomical and physiological inquiry, he arrives at the following conclusions: 1. That the flaps are slightly drawn upwards, and to the sides, when the levator palati contracts. 2. That when the levator palati, and palato-pharyngeus, act strongly and together, the flaps are so forcibly drawn from the mesial gap, that they can scarcely be distinguished from the sides of the pharynx. 3. That the flaps are forced together, and the edges come into contact, when the superior constrictor muscle contracts during the act of deglutition. 4. That the circumflexus palati possesses but a feeble power over the flaps. Lastly, the fibres of the palato glossus were very im-

perfectly developed in the specimen in his possession. The chief object of his paper is to communicate a novel plan of operating in staphyloraphy, founded on the above investigations, and which he has put in practice, with most satisfactory results, in two cases, during the last twelve months. The principle of his new proposal is to divide those muscles of the palate which have the effect of drawing the flaps from each other, and widening the gap between them when they contract; so that the stretched velum may be in a state of repose, and the pared edges may not be pulled asunder by any convulsive action of the parts, during the process of union. In other words, he advises, as an important accessory to the operation of staphyloraphy, the division of the levator palati and palato-pharyngeus muscles, and, if requisite, the palato-glossus. In bringing forward this plan, he reviews the different modes of operating which have been produced by numerous distinguished surgeons who have written on the subject: and he concludes by entering into several minute details regarding the steps in his own operation, and by describing the particular forms of instruments which he had found best adapted for his proceedings.

The preparation of cleft palate, a dissection of the parts in the usual condition of the throat, a variety of diagrams, instruments, &c., were on the table, to illustrate the views of the author.

The President inquired if any member present had dissected a cleft palate, and directed attention to the dissection of Mr. Fergusson.

Mr. Caesar Hawkins inquired the ages of the patients operated on, and whether the hard palate, as well as the soft, were involved in the deformity.

Mr. Fergusson replied, that in his operations he had been guided by a rule generally followed in these cases by surgeons; he had not operated until the patients were of an adult age. In both cases, little of the hard palate was involved in the fissure. Such a condition, he thought, made little difference regarding the proposed operation, for, as he had pointed out, the motor power influenced only the soft tissues; should Warren's operation be resorted to, it was quite clear that the tissues dissected from the bones would be subjected to no motory influence. He pointed to some casts before the Society, which exhibited the fissure in the bony palate, and remarked, that an observation of these would shew that when the soft tissues were dissected, and brought downwards, they would easily meet in the mesial line.

The President pointed out the chief features and novelties in Mr. Fergusson's paper, as consisting in the explanation given of the mode in which persons with fissured

palate were able to swallow food without its passing into the nostrils, and the division of the motor muscles of the palate. Did the silence of the members on the subject indicate that they were unprepared to discuss such novelties?

Sir G. Lefevre was sorry that so important a paper appeared to excite so little discussion. He inquired of the author the length of time that elapsed before the fissure was quite closed, and how far the operation had influenced speech?

Mr. Fergusson had referred to the two cases in his paper rather with the view of producing living evidence respecting his operation, than for the purpose of entering into a minute history of the cases. He would, however, briefly describe these cases to the Society. One of the patients was a youth, about seventeen years of age, who had a congenital defect of the palate. He was anxious to make his way in the world, and was desirous, as he had interest, to go into the army, but his deformity rendered his success almost hopeless. When he (Mr. F.) first saw the case, the gap was so extensive, that he was not sanguine as to the success of an operation in producing union, or improving the voice, for experience had convinced him that the latter was scarcely to be more than hoped for. The patient, however, was willing to abide the result of any operative procedure, and the operation described in the paper had accordingly been performed. A part of the gap had opened again, but a second operation was some months afterwards performed, and the success had been complete. The tones, and mode of articulation, appeared at first to be somewhat improved, but soon returned to their former imperfection, and so remained until he placed himself under a teacher of elocution, which he did eight months after the operation. Under the tuition of Mr. Hunt, in a very brief period, the improvement had been truly astonishing, and he (Mr. F.) had no doubt would eventually be such as would enable him to enter the army. The second case was that of a young lady, the same age as the former patient, and who seldom or never attempted to speak in company, so conscious was she of the miserable defect under which she laboured. She cheerfully assented to the operation, which in her case had been successful. There still, however, remained, in this case, a slight aperture anteriorly; this, however, would doubtless soon be closed. Surgeons acquainted with these operations knew well that they occasionally required repetition, and that apertures would sometimes remain for a considerable period afterwards, until closed by the use of the cautery, or of caustic. It might be said that this patient required to be taught to speak, and this, he

thought, she would soon do, if placed under a good teacher of elocution. He had, when Muller and Warren were in this country, inquired of these distinguished surgeons their experience respecting the influence of the operation for cleft palate on the voice, and both these gentlemen replied that they had reason in some cases to be disappointed. A few days after the operation would determine its success, for if, after the stitches were removed at the expiration of six to ten days, the parts kept together, a perfect cure was pretty certain. He referred to a case lately related to him by Sir B. Brodie, in which, after the operation, no improvement in articulation took place until the patient had taken lessons in elocution. He afterwards spoke tolerably well, and obtained a commission in the army.

Dr. Gregory inquired if any mechanical apparatus had been resorted to before the operation in the cases just related; if so, what was its effect? and what was the experience of the author of the paper respecting mechanical contrivances in cleft palate generally?

Mr. Partridge inquired if there were any difficulty in elevating the soft palate, or in deglutition, after the operation?

Mr. Fergusson replied that in the cases he had just related, no kind of apparatus had been used before the operation. He had no experience on this point; Mr. Partridge's question involved a controversial point, for the most eminent physiologists differed with respect to the action and condition of the soft velum during the act of deglutition. He, himself, considered that there was little motion in it during that act. In a patient whom he had the longest opportunity of observing, the motions were much the same as in the natural palate. He could observe the action of the levator palati as readily as in the well-formed structure. He had no doubt that the levator palati had formed new adhesions to the velum. It was worth noticing, that in the early attempt at deglutition succeeding the operation, the morsel was slipped back in the most gentle manner, which was attributable to the tender state of the parts, and the cautions of the surgeon; in addition to these the soft palate was at first so hardened and thickened, that it was used with difficulty, but in a short time it assumed a more natural condition, and the patient could then both swallow and speak with great facility.

Mr. Shaw observed that the author had laid little stress on the action of the circumflexus or tensor palati, in his paper; this might be supposed by some to be a weak point, as the action of this muscle might tend to the separation of the sides of the wound. Much reflection on this subject, however, had led him to attach little impor-

tance to the effects of this muscle on the soft palate.

Mr. Fergusson had mentioned in his paper his opinion that the levator palati exerted but small influence over the moveable parts. He had, at one time, held a contrary opinion, but observation had convinced him the influence of this muscle would be unlikely to interfere with the success of an operation. He was convinced on this point, by the shape, development, and course of the muscle. He referred, in confirmation of this opinion, to a dissection of the muscle in the natural state. The name tensor, implied a power which the muscle did not really possess; the motion was scarcely to be discovered.

Mr. Partridge remarked that the tensor palati was very small in the preparation which had been exhibited.

Mr. Fergusson was of a different opinion, for he thought the muscle larger than usual, and that its action was more apparent in the cleft than in the natural palate.

The next meeting of the Society will be held on Tuesday, the 14th of January, 1845.

PHYSICAL SOCIETY OF GUY'S HOSPITAL.

J. S. STREETER, Esq., in the Chair.

Dec. 14th, 1844.

MR. ILIFF, of Newington Butts, read a paper, in which he brought before the notice of the Society the consideration of those membranous-like formations which are not unfrequently passed by patients mingled with their alvine evacuations. He regarded the mucous membrane of any part of the intestinal canal from the duodenum to the sigmoid flexure of the colon, as capable of originating them when exposed to adequate causes of irritation. Their exact nature he would not take upon himself to decide, but purposely left that part of his subject for elucidation in the discussion which he hoped to elicit. This peculiar disease of the intestine according to his observations occurred most frequently in women, had always been preceded by dyspeptic symptoms, often of long continuance, and was best combated by undeviating attention to diet, soothing measures, light tonics and slight astringents, as Liq. Potassæ and Balsam Copaiba, and the careful employment of only the mildest aperients. He read the particulars of eight or nine cases which had come under his care, all of which, save one, the subject of malignant disease of the os uteri, and another which had passed from his care, had regained and preserved a tolerably good state of health. The paper and cases were illustrated by numerous preparations and drawings. In the course of his observations, Mr. Iliff

alluded to the cases of analogous formations by the bronchial membrane, one read by himself in 1822 (*Med. Rep.* Vol. 18), those read by Mr. North, before the Royal College of Physicians, and recorded in the *LONDON MEDICAL GAZETTE* in 1838, and those by Dr. Reid in the last volume of the *Med. Chir. Trans.*—to the special papers on their formation by the mucous membrane of the duodenum by Dr. Powell in 1818 (*Trans. of the College of Physicians*, Vol. vi.) and by Dr. Todd of Brighton, under the name of Follicular Duodenal Dyspepsia (*Cyclopedia of Practical Medicine*), and particularly to a case that fell under the observation of Dr. Mann Burrows, in 1814 (*Med. Rep.* Vol. 1), at whose request Dr. A. Thomson instituted a chemical examination of the substance passed, and found it “consisted chiefly of animal mucus, combined with a small portion of albumen and gelatin.”

He concluded by drawing attention to a similar case just published by Dr. Arthur Farre, in the *Trans. of the Microscopical Society*, who from the examination he has instituted, believes the formation is one of a confervoid type—an oscillatoria in fact—the result of sporules swallowed by the patient in her ordinary drink. An opinion at which Mr. Iliff expressed his surprise, and could not adopt, unless confirmed by further microscopical examinations, and also by chemical inquiry. Drawings of a conferva, and of the supposed species of oscillatoria, were also exhibited, but the specimen which had been lent by Mr. Sowerby for the occasion, could not then be examined, for the key of the hospital microscope was not forthcoming.

A discussion ensued, in which Drs. Brereton, Edmund, Birkett, Oldham, Munk and Chevers, and Messrs. Greenwood, Blenkarne, Lloyd, and Birket, took part. The essential dependence of these membranous formations on precedent irritation or inflammation—the degree of the latter, and its acute or chronic character—the modification of these membraniform products by respective peculiarities in the minute anatomy of the respiratory or intestinal membrane from which they derive their origin—and the probability of their being the result of two different morbid conditions of the mucous membrane; the one, irritation, producing a mere thickened epithelial coat of the tube, as in the so-called cases of bronchial polypus, while the other was a real acute inflammation attended with effusion of fibrine, as in croup, formed the most interesting topics of debate. Mr. Blenkarne related a case where a cast of the meatus auditorius externus had been thrown off. Dr. Oldham particularly contended for the two-fold morbid origin of pseudo membranes, by an especial reference to observations on membranous

menstruation. He had lately had the opportunity of microscopically examining this morbid structure in the uterus of a woman who died during the catamenial period, and had found it to be of epithelial formation. The hour allotted for discussion having elapsed, the cordial thanks of the Society were voted to Mr. Iliff, and the President announced that the next meeting would take place on Saturday, the 4th of January, but did not name the subject for discussion.

DR. GUY'S REPLY TO MR. TAYLOR.

WE last week stated that we had closed this unpleasant subject. Dr. Guy considers that he has not been fairly treated, and requests us, in justice to him, to insert a letter in reply to Mr. Taylor, with additional remarks upon the notice of his book contained in the number of last week. We are willing to oblige Dr. Guy in his request, and have inserted his communications.

To the Editor of the Medical Gazette.

SIR,

MR. TAYLOR'S letter of last week puts an end to all controversy between my reviewer and myself, and renders the publication of the last letter which I had the honour of addressing to you unnecessary.

Mr. Taylor fairly takes upon himself, though in a very modified and subdued form, the unmeasured invective of the review, which I never regarded in any other light than as the exaggerated and distorted representation of Mr. Taylor's sentiments. His charge against me is to the effect, that the “*Manual of Medical Jurisprudence*” has been much more frequently used by me, without reference or acknowledgment, than is either proper or becoming in one writer following another so closely on the same subject;” and in the last paragraph of the letter the charge is limited to the statement that my “*Chemical Toxicology*” is substantially abridged from that lately published in the ‘*Manual*,’ with occasional interpolations from Christison and Beck.” This, then, seems to be the extent to which Mr. Taylor seems ready to support the allegations of the review.

I must first express my surprise that Mr. Taylor, who, I presume, has not made this charge without reading my book with some attention, should designate my constant and full references to Christison's work as “occasional interpolations.” Why, my quotations from Christison are three times as numerous, and ten times as important, as those from the *Manual*. I not only constantly refer to him for cases, but for more complete and detailed information on all the

more important points of toxicology. Beek is quoted only once. This extraordinary misrepresentation of Mr. Taylor's must convince any impartial man that he writes under the influence of some feeling very unfavourable to accuracy. He is evidently labouring under some strange mistake, or he is the dupe of a "foregone conclusion."

Now, as to the remainder of the charge. My "chemical toxicology," it appears, is an abridgment of Mr. Taylor's. I presume that this phrase is synonymous with the more common expression "tests for poisons." If so, I have merely to remind Mr. Taylor that for some few years past I have been in the habit of exhibiting to my class the tests for poisons, of explaining the necessary precautions, and of pointing out the fallacies which attach to them. With all my proneness to plagiarism, therefore, my knowledge of the subject prevented me from gratifying my favourite propensity to any great extent. If Mr. Taylor had made some important chemical discoveries, or suggested a score or two of new tests, I should of course have appropriated them without a moment's hesitation; but as I found only two unimportant suggestions, I made an open display of my honesty, and quoted them in due form. To keep up appearances, I put one of them to the test of experiment, and was somewhat surprised to find that it did not answer. I was not aware, till I read Mr. Taylor's letter, that the accident of priority of publication conferred the right of appropriating the common and familiar facts of chemistry. I had innocently regarded them as public property, and am not even now quite convinced of the contrary. If Mr. Taylor should succeed in establishing this monopoly, and I in reforming my bad habits, matters will be greatly simplified. One comprehensive reference will suffice.

In truth, Mr. Taylor's Manual was a great embarrassment to me. I knew that if I did not refer to it, I might, by some untoward coincidence, strengthen the premeditated charge of plagiarism. For instance, had I cited the familiar case in which the question of the influence of habit in lessening the effect of opium was raised in a Court of Law, I should have added force to the felicitous parallel of my reviewer. If, on the contrary, I had made no reference to the Manual, or if I had followed Mr. Taylor's own example, and, instead of saying Mr. Taylor gives this case, or thinks this or that, I had said such and such a case had been recorded, or such an opinion had been entertained, I should have been accused of passing over in silence the name of a contemporary. I could only avoid the appearance of copying Mr. Taylor's arrangement, by departing as widely as possible from Dr. Christison, whom I had adopted as my model. I must have put the vegetable poisons before the

mineral, or zinc before arsenic, or I must have mixed all the poisons together, or invented some unsound arrangement of my own. Again, in treating the individual subjects, I must have departed from the plan of the first two parts, and of my lectures, and have blended tests, symptoms, post-mortem appearances, smallest fatal dose, average duration, and treatment, in undistinguishable confusion. By these means, and by these alone, could I have escaped the charge of plagiarism. The alternative was a confused contrast to the first two parts of my book, or the lash of the reviewer, and the accusation of Mr. Taylor. It required some courage to prefer the last, but I embraced it without hesitation. By means of a new arrangement of the tests for poisons, the invention of a new form of chemical table, sundry extensive analyses of cases of poisoning, a novel suggestion here and there, and an occasional experiment, I contrived to give an air of originality to the "Principles," to which, in my partiality for my own production, I attach some slight importance.

One word about the letter to the *Lancet*. For reasons which will be easily understood, I did not state all the circumstances which led to that communication. I now supply the deficiency. A mutual friend of Mr. Taylor and myself, whose name it is unnecessary to mix up in this controversy, wrote to me to state that Mr. Taylor had pointed out to him several passages in my second part which had been taken with little or no alteration from the first volume of the "Elements of Medical Jurisprudence." I lost no time in explaining the circumstance both to the friend in question, and to Mr. Taylor, and I have the best reason to believe that my explanation was satisfactory to both gentlemen. After this communication with the party most interested, I thought to hear no more of my unintentional appropriations, but finding that the subject was talked about, I wrote the letter alluded to. It is necessary to state that my friend assured me that he had not opened his lips on the subject.

The letter which I addressed to you the week before last, renders a longer reply to Mr. Taylor's charge unnecessary. I have only to add, that I justify the use I have made of his "Manual," and am willing to abide by the sentence which the profession may pass upon me. What I have done, I have done deliberately, and with a full conviction that, do what I might, I could only escape censure by consenting to abandon the order and arrangement of which experience had taught me the value.

I have the honour to be, sir,

Your obedient servant,

WILLIAM A. GUY.

15, Bloomsbury Square,
December 9th, 1844.

The following is Dr. Guy's second letter in reference to the criticism contained in our last number.

DR. GUY'S REPLY TO THE "REMARKS."

To the Editor of the Medical Gazette.

SIR,

THE "Remarks on Dr. Guy and his Reviewer," in the last number of your journal, took the place which I thought I had secured in your pages by the early transmission of my reply to Mr. Taylor's letter. I trust that that reply will appear in your number of next week, and I take the liberty of requesting the insertion of the following additional observations on the "Remarks." I am placed in a very embarrassing position between mirth and anger. I do not know whether to be amused by the ridiculous claims to originality set up on behalf of Mr. Taylor, or angry at the disingenuous way in which that claim is supported; and I believe that the profession is in the same predicament. If Mr. Taylor had made as many discoveries as Sir Humphry Davy, as many inventions as Wollaston, and proposed as many new tests as Orfila and Christison combined, he could not be a greater man than his critics and commentators would make him out to be. If I had stolen from him as many discoveries as all these great men together have made, he could not be more aggrieved than he represents himself to be, by my alleged appropriation of chemical equivalents, simple rules of proportion, familiar tests, and distinct headings. This it is that moves my mirth. My indignation is roused by the intentional misrepresentations of the author of the "Remarks." I may add that he must be a very unsuspicious person who does not imagine that he sees in these "Remarks" the handiwork of Mr. Taylor himself. The writer, whoever he may be, has Mr. Taylor's authority for one, at least, of his statements, and he knows too much of Mr. Taylor's history, and of

Taylor, p. 147.

Objections. Corrosive sublimate is volatile like white arsenic, but it differs from it in all its other properties. It is very soluble in water, insoluble in potash, which turns it of a yellow colour, while hydrosulphuret of ammonia turns it black. Indeed, it may be said that there is no substance but arsenic, which possesses the three first characters mentioned; they should, however, be taken together.

The fraud which has been committed is obvious at a glance. The passage from the "Principles" is part of a process of elimination; that from the "Manual" is the commencement of a series of objections. The very order of the tests is a deception.

mine, not to be readily identified. Be the author, however, who he may, I accuse him of a series of deliberate misrepresentations, of intentional suppressions of the truth, and of equally intentional suggestions of what he knows to be false.

I make this statement deliberately, and prove it by referring to the parallel which he has drawn up with so much apparent care, but which, in the narrow limits of a page and a half, furnishes a complete compendium of every vice, except that of plagiarism, which can be practised with the pen.

The second edition of Christison, like the first and third, contains these words:—"The solution of the oxide of arsenic in boiling water yields minute crystals on cooling, which, when their form is defined, are octahedres." (p. 229.) These words begin a paragraph, and that paragraph follows the one which treats of the solubility of the poison in water. Does the author of the "Remarks" still assert that this property of arsenious acid is not to be found in Orfila or Christison, but only in the Manual? Does he also persist in claiming as Mr. Taylor's property the fact, that arsenious acid combines with alkalis, forming soluble arsenites? He may as well lay claim to the A B C. It is very unkind of the author of the "Remarks" thus to turn Mr. Taylor into ridicule.

So much for the first misrepresentation. The next is an improvement upon it. Under the head "Powder," there is marked in italics, as being taken from the Manual, the following sentence. "Add liquor potassæ, no change. Corr. sub. turned yellow;" and on the opposite side, "Corrosive sublimate, volatile like arsenic, but turned yellow by potash." Now, an unsuspicious reader would not hesitate a moment to accept both these passages as true and ungarbled abstracts. No such thing. They are two admirable examples of the *suppressio veri*. The passages from which they are taken ought to be placed side by side.

Guy, p. 453.

The effect of heat does not prove the powder in question to be arsenious acid, for bichloride of mercury, and calomel, also sublime unchanged. To another portion of the powder add liquor potassæ. If the powder be arsenious acid, no change takes place. Corrosive sublimate is changed to a yellow, and calomel to a black colour.

They do not stand in my work as 1, 2, 3, 4, 5, but heat and caustic potash are used as preliminary tests, on the supposition that the nature of a white powder is unknown; and tests 3, 4, and 5, are used to confirm the indications afforded by the first two tests.

After these illustrations of the scrupulous care and regard to truth of the author of the "Remarks," your readers will not be unprepared for the assertion, nor much surprised at the plain language in which it is couched, that the statement that the properties of the oxide of cadmium are "copied from the Manual *ipsissimis verbis*," is a deliberate falsehood, admitting neither of palliation nor excuse. See "Principles" p. 454, and "Manual," p. 147.

Having now shewn the dishonesty of my anonymous accuser, I should treat the rest of his production with the contempt it deserves, but that the "authority" with which he uses Mr. Taylor's name, and his unusual familiarity with the relation in which I have stood towards that gentleman, gives it all the importance of a manifesto from Cambridge Place.

It appears that there are stronger instances of plagiarism than the passage on habit which recoiled so pleasantly on Mr. Taylor. Why, then, did the reviewer make so unlucky a selection? Why does not the author of the "Remarks" favour us with some of those stronger instances? The *ipsissima verba* must be easy enough to find. Why not have quoted them? Simply because assertion is much easier and more convenient than proof.

I pass over the alleged "misapprehensions" and "mystifications" about arsenite of copper and sulphuret of lead, the very original formula which the writer of the "Remarks" has Mr. Taylor's authority for asserting to have been used by him in his lectures at Guy's Hospital since 1831, and which it appears that I have taken from him without acknowledgment, and the asserted appropriation of chemical equivalents, as trifles which he may amuse himself with as long as he pleases. If he will persist in claiming these familiar facts and every-day calculations, he will have enough to do to defend his monopoly, and must forthwith make up his mind to the trouble and expense of a *scire facias*. I, for my part, am very angry with the chemists of the last century for the unwarrantable use they have made of the Manual, and I fear that their bad example will be followed till the end of time. I begin, indeed, to have some misgivings as to the honesty of our arithmeticians. The rule of three is evidently in danger of being made into a monopoly. Once more, I would remind the author of the "Remarks" that whatever authority he may have received as to the chemical application of the rule of three, he must have greatly exceeded his powers in thus turning Mr. Taylor into ridicule.

The author of the "Remarks" will doubtless be greatly surprised to hear that I do not acknowledge my obligations to Mr.

Taylor in the matter of the "distinct chapters, sections, or paragraphs." He may rest assured that if I had preceded him as a writer on toxicology, and had never even seen or heard of him, I should have forestalled him. No one who has read the first two parts of my work can doubt the truth of this assertion, and the very turn of my mind, and my mode of collecting and arranging information, render the adoption of minute subdivisions and distinct headings inevitable. I have myself some intention, by way of amusement, of claiming the adoption of such distinct headings, in treating the subject of infanticide.

The writer of the "Remarks" hardly knows how to receive my assertion "that the order in which the several tests are placed is one peculiar to myself, and which I have always followed in my lectures." It is passing strange that the acuteness which discovered *ipsissima verba* in the description of the crusts of cadmium, and the industry which brought together the *disjecta membra* of the parallels, could find no illustration of the truth of this statement. It was not necessary that he should con my book "paragraph by paragraph, page by page," in order to find some clue to my meaning. He missed it for the same reason that he passed over the test in the second edition of Christison. It looked him in the face as he was garbling the tests for arsenious acid. Let him turn to page 413 of the "Principles," and he will be enlightened as to my meaning, and will understand the "occasional transposition of an experiment in the series," and the reason for it.

The last paragraph but one of the "Remarks" places Mr. Taylor in a dilemma from which, I fear, he will find some difficulty in extricating himself. Either he himself, or some one entirely in his confidence, and writing under his authority, is the author of the "Remarks." On the first supposition I have accused him of deliberate misrepresentation; on the last, he has been very unfortunate in the choice of a confidant. In any case, I greatly prefer my position to his, and have reason to congratulate myself that one at least of my accusers stands convicted of a worse crime than that of plagiarism.

I have the honour to be, sir,

Your obedient servant,

WILLIAM A. GUY.

15, Bloomsbury Square,
Dec. 14, 1844.

REMARKS.—We will give Dr. Guy the benefit of his statement, that Dr. Christison, and probably other chemical writers before him, were aware that arsenious acid was deposited in octohedral crystals from its solution. We merely invited our readers to

contrast generally the analytical processes pursued by the four different authors. And we repeat, that differences will be found to exist among them, as much with respect to new applications of well known chemical facts, as with the invention of entirely new processes. This answer applies also to his remarks on the arsenite of potash. It has been long known that arsenious acid is soluble in caustic potash. Mr. Taylor, and Dr. Guy give it as a test for powdered arsenic. Orfila and Dr. Christison do not.

The passages quoted by Dr. Guy relative to corrosive sublimate will at once show how he has treated the Manual. He omits to state that no such passages occur in Christison, Orfila, or any other work, treating of the tests for arsenic,—the great object of our quotation. He states, that his paragraph is “part of a process of elimination,” and that “the very order of the tests is a deception.” We admit, but not in the sense he intends, both of these positions; but this is no answer to the charge, that he

Taylor, p. 147.

The oxide of cadmium may be reduced by a similar process, but the metallic sublimate is wholly different from that of arsenic: it has a tin-like lustre, and has a brown margin of reproduced oxide. There is no odour of garlick during the reduction of oxide of cadmium, and on heating the metallic ring it is not wholly volatilized like arsenic, but converted to a ring of brown oxide. Oxide of cadmium is of a brown colour; it cannot be volatilized on platina by the heat of a spirit lamp; it is quite insoluble in potash, but easily dissolved by nitric acid. * * Oxide of cadmium is, moreover, a very rare substance—it is difficult to meet with it.

We simply ask our readers to compare these two passages, and bearing in mind that we have all along alleged that Dr. Guy has abridged the descriptions of facts contained in the Manual, we further ask them to say, whether our reviewer was far wrong in stating that Dr. Guy had copied this paragraph from the Manual “*ALMOST ipsissimus verbis!*” And yet Dr. Guy has the courage to assert, that the allegation is a “deliberate falsehood, admitting neither of palliation nor excuse.” We cannot fill our pages by making further quotations; but if our readers will take the trouble to refer to the tests for *arsenic acid* they will find that Dr. Guy is equally unfortunate in his reference to this part of our criticism. Let the tests for oxalic acid, and, indeed, of all the poisons contained in the two works, be compared, and with few exceptions they will be found very similar, so similar as to bring home conviction to our minds that our charge of plagiarism was well founded. Whether Dr. Guy uses tests in a different “order,” or employs them as

has substantially taken the facts there stated from the Manual. If Dr. Guy considers that it is a sufficient answer to say, he uses the tests in different order, we cannot agree with him.

We alleged that the objections and answers respecting *oxide of cadmium* were “copied from the manual almost *ipsissimus verbis.*” Dr. Guy omits the word “almost,” and states this to be “*a deliberate falsehood, admitting neither of palliation or excuse.*”

We first distinctly affirm, what Dr. Guy is wholly unable to deny, that these objections and answers occur in no other works on toxicology but his own “Principles,” and Mr. Taylor’s “Manual.” Whatever may be said about octohedral crystals and arsenite of potash, this is a fact which he has not even attempted to controvert. In order to see whether the “deliberate falsehood” lies with our reviewer or his accuser, we here give the quotations, to which we referred in our last number, *verbatim*, and to which Dr. Guy boldly refers our readers.

Guy, p. 454.

The oxide of cadmium may be reduced so as to form a crust. In answer to this objection, it is sufficient to state, that the oxide of cadmium is extremely rare, and of a brown colour—that the crust is bordered by this brown oxide—that it gives out no garlick odour, that it is not readily volatilized like arsenic, and that the ring of metal when heated is converted to the brown oxide instead of being sublimed as a white powder, or a ring of octohedral crystals.

“part of a process of elimination,” we still find, what we originally asserted, that the third part of his book bears a close resemblance to the corresponding part of Mr. Taylor’s volume. So far as we are concerned the matter is here closed: we cannot insert any more communications on this subject. Our pages have been occupied to a somewhat unreasonable extent with the discussion.

PROPOSAL

TO INCORPORATE THE EIGHTEEN THOUSAND LICENTIATES OF THE HALL INTO A ROYAL COLLEGE OF APOTHECARIES.

To the Editor of the Medical Gazette.

SIR,

THE contemplated degradation and ruin of the surgeon-apothecary, by the proposed enactments of Sir James Graham’s bill, is so palpable, and so generally acknowledged, that it appears quite superfluous to attempt

the establishment of a case: whether this impending degradation and ruin be accidental, (which it is barely possible to believe), or intentional, it is of little moment to inquire; *the fact* is all with which at the present juncture we have anything to do, and that does not appear to admit of doubt. I will, however, for satisfaction sake, briefly set down what is contemplated for the surgeon-apothecary by the impending law.

1st. All restriction upon unqualified practitioners is removed.

2nd. He is virtually deprived of the power of educating his own class.

3rd. The law takes from him his present titles, and gives him nothing, or as good as nothing, in exchange.

For he finds himself excluded from the council, excluded from any share in determining the education, or influencing the character of the examination of his own class, without any real participation in the examination itself; and as regards the future licentiate, after his education and examination have been directed by the Colleges of Physicians, the bill secures him *no admission into either of the bodies*.

There is a point in medical practice, alike familiar to all, which occurs when the practitioner has made himself master of the case; and the point is this—what is to be done?

That the case before us admits of an easy and certain remedy I have no doubt. The remedy is *incorporation*. Dr. Webster, Mr. Ryan, and an anonymous writer in the *Lancet*, propose incorporation of the general practitioners into a "Royal College of Medicine and Surgery." With all deference to these respectable individuals, I am decidedly of opinion that *any and every attempt* to establish such a body would *fail; utterly fail*—the attempt was made, vigorously made, more than thirty years ago, and *failed*. The Apothecaries' Act was, indeed, the consequence of that movement, and the only consequence.

The great impediment to the enterprise was the same as exists at the present time, with the exception that it is infinitely more formidable and impregnable; the proposed institution would be a *rival* to the Royal College of Surgeons. Who can for a moment doubt the influence of this body? Who can doubt but that that influence would be vigorously applied? Who, in the present state of our affairs, could doubt but that that influence would be *sufficient to defeat* the utmost exertions of its *enemies to ruin* its establishment.

In my humble opinion *this is not* the remedy, but, with your leave, I will tell you in what the remedy does really consist, against which no such opposition need be apprehended, the sure and certain effect of

which is such as need not to be questioned; which is so reasonable, so just, and so especially suited to the case, that not even the framers of the *bill* (I was about to write the *accursed bill*) shall be found to have courage to refuse, if vigorously sought, and if applied for *without delay*.

The remedy I have to propose is the incorporation of the *eighteen thousand licentiates* of the Hall into a "*Royal College of Apothecaries*," and to change the title of the trading Apothecaries' Company into the "*Worshipful Company of Chemists and Druggists*." By this simple means we obtain what is clearly wanting, a *third estate* in the medical institutions of the country, not the anomalous mongrel kind of thing proposed to be created by the bill in the person of the "licentiate in medicine and surgery, for whose education the provisions of that bill are so *vague and unsatisfactory*, but, a clearly defined, well and thoroughly educated body of medical practitioners, to which the community are accustomed, who, with or without the additional qualification of being a member of the Royal College of Surgeons, shall be in every way *worthy of the respect* of his colleagues, and of *public confidence*. This Royal College of Apothecaries must have identically the same power and control over the education of its class as is enjoyed by the other institutions; they must have a voice in the Council of Health, and in every respect be placed on the same footing as the Royal College of Surgeons. It must have a council and a court of examiners; all present licentiates must be members, and all eligible to be elected to fill the offices of the institution. Candidates having passed their examination to be entitled to membership, and the required "letters testimonial."

This Royal College of Apothecaries being established, the medical institutions of the country would stand thus:—

The Royal College of Physicians.

"	"	Surgeons.
"	"	Apothecaries.
"	"	Chemistry.

The chemists have already obtained a Royal Charter of Incorporation. Would the list be improved by erasing the Apothecaries? What have the Apothecaries done that they should be thus signally victimised? The public cannot do without them, and though the Apothecaries' Act be repealed, Apothecaries will still continue, though a degraded order. Let them be incorporated, as I have suggested, and then the work of legislation becomes comparatively easy; at any rate the *great degradation and impending ruin* with which we are so *fearfully threatened* would be averted, and the condition of our order

greatly improved. Should the licentiates of the Hall, (for it is to them that I more particularly address myself) be of the same opinion, I say let us earnestly co-operate for the attainment of our object. The Institution I propose accomplishes, or may be made to accomplish, every purpose. It makes the profession complete; it supplies all the wants of the public; it makes the apothecary respectable; and gives to the general practitioner a double claim to the confidence of the community. It leaves the province of pure surgery open to those who choose to follow it, and the doctor of medicine altogether unmolested.

It may be urged that I have laid the foundation of a feud with the "*Society of Apothecaries*," in proposing to change the title of their Company; I know not how that may be, for I have had no correspondence with them; but if they are sincere in the last paragraph of their able and lucid explanation of the bill, which has only been in my hands a few days, and which it is the bounden duty of every one of their licentiates to read, and the perusal of which has given rise to this letter, they will not *vexatiously* oppose any plan, affecting themselves in so slight a degree, that it is calculated to promote the *public good*. The Society of Apothecaries rightly considered are only a company of wholesale and retail druggists, and in sober honesty should have no objection to the change proposed; the change is *important*, as thereby the title of Apothecary is made more *respectable*, and the anomaly of a Royal College of Apothecaries, and a trading Apothecaries' Hall, existing simultaneously, could not otherwise be got rid of; the one being, as before stated, a trading company, the other an institution *especially devoted to the promulgation of medical science*. I have studiously confined myself to the general principle; I might otherwise have extended my letter to a length inconvenient to your pages. I am aware that the proposition will come in the shape of a novelty; it is, however, no novelty with me; the idea has prevailed in my mind since the first publication of "the bill."—I am, sir,

Your obedient servant,

JAMES COLE,

Member of the Royal College of Surgeons,
and Licentiate of Apothecaries' Hall.

Bewdley, Worcestershire.

NOTE FROM DR. BRERETON.

To the Editor of the Medical Gazette.

SIR,

MAY I request the earliest insertion of the following correction of an important error, which occurs in your report of the discus-

sion on Aneurism, which took place at the Guy's Physical Society, Nov. 30th.

It is there stated, "A case of thoracic aneurism in St. Bartholomew's Hospital, where Mr. Paget, with the sanction of Dr. Latham, had employed venesection *fifty times*, was related by Dr. Brereton to have proved *completely successful*, as demonstrated when the patient died of concomitant disease of the lung two years after."

What I did say was, "that I had been informed that Mr. Paget, under Dr. Latham's sanction, had, in a case of thoracic aneurism, employed frequent minute bleedings, amounting in all to upwards of *thirty*; that the prominent symptoms of aneurism were allayed; and that, when the patient died some time after of phthisis, it was found that the sac had contracted, and that the aneurism was apparently progressing to a cure."

In justice, however, to Mr. Paget and the medical public, I must now add, that even my corrected statement is not quite satisfactory; for Mr. Paget states, "The man was bled not more than *twenty times* in about six or seven weeks; and the *aneurism was not cured*. Its progress appeared to be arrested, but it existed as an aneurism when the patient died."—I am, sir,

Very obediently yours,

J. CADELL BRERETON,

M.B. Cantab.

Guy's, Dec. 18, 1844.

EVOLUTION AND DELIVERY WITH PRESENTATION OF THE ARM AND SHOULDER.

A HEALTHY woman, who had already had several children without difficulty of any kind, was taken in labour again, and besides the waters, lost a considerable quantity of blood. When seen first, the right upper extremity of the foetus was found projecting from the external parts of the mother: the pains at this time had almost ceased, but on an attempt being made to introduce the hand, and turn, they came on again with such violence that the attendant was on the point of taking away some blood to moderate their force. The mother now said she felt the child advancing, and in fact the right shoulder and collar-bone were forced beyond the vulva: the lower extremities and buttocks were at the same time forced into the hollow of the sacrum, and by and by the right ramus of the lower-jaw came into sight, the shoulders and arm having receded. But little effort was required to disengage the breech, upon which the child was quickly born; but it was dead. The placenta followed, and an hour afterwards the woman felt herself very comfortable."—DR. SUSSEWIND, in *Caspar's Wochenschrift*, No. 23.

COMPARATIVE ANALYSIS
OF
THE FOOD CONSUMED AND THE
EXCREMENTS PASSED BY A
TURTLE DOVE ;

UNDERTAKEN WITH A VIEW TO ASCERTAIN
WHETHER OR NOT THERE IS ANY EXHA-
LATION OF AZOTE DURING RESPIRATION
IN THE GRANIVORA.

By M. BOUSSINGAULT.

AN exhalation of azote is pretty generally acknowledged, at the present time, as a consequence flowing from the experiments of Dulong and Despretz. Some years ago, M. Boussingault was himself led to adopt this inference as correct ; but certain motives

have lately induced him to study the matter anew.

Every precaution was of course taken to secure uniformity of circumstance and condition. The millet seed with which the bird was fed was from one parcel ; it was carefully kept from moisture, none was lost, &c. The excrements fell upon a glass plate at the bottom of the cage ; they were weighed moist, and then dried at a moderate temperature. The temperature of the room in which the dove was kept never exceeded from 10° to 11° C. (50° to 51·8° F.) The experiments were divided into two series ; the first comprising a period of five, the second one of seven days.

The results of the two series of experiment^s are comprised in the following table of—

Food consumed and Excrement passed by a Turtle Dove during five days.—1st Series.

Weight of Millet Seed, presumed absolutely dry.	Principles contained in the Food and Excrement.					Weight of the Dove.	
	Carbon.	Hydrogen.	Oxygen.	Azote.	Salts.		
Grms. 65·91	Grms. 30·37	Grms. 4·15	Grms. 27·52	Grms. 2·17	Grms. 1·70	At first	Grms. 187·90
Dry excrement 15·04	5·96	0·77	5·15	1·39	1·77	At the end	186·27
Principles eliminated in five days	24·41	3·38	22·37	0·78			

Food consumed and Excrement passed by a Turtle Dove during seven days.—2d Series.

	Principles contained in the Food and Excrement.					Weight of the Dove.	
	Carbon.	Hydrogen.	Oxygen.	Azote.	Salts.		
Grms. Dry millet seed 101·15	Grms. 46·60	Grms. 6·36	Grms. 42·24	Grms. 3·34	Grms. 2·61	At first	Grms. 186·70
Dry excrement 24·056	9·77	1·20	8·31	2·20	2·58	At the end	185·47
Principles eliminated in seven days	36·83	5·16	33·93	1·14			
Food consumed in 12 days 167·06	76·97	10·51	69·76	5·51	6·31	Weight of Dove at commencement of whole series. 187·90 grs.	
Principles eliminated in 12 days	61·24	8·54	36·30	1·92			
Principles eliminated in 24 hours	5·10	0·71	4·69	0·16			
Combustion of Carbon per hour	0·212					At end of ditto.	185·47 grs.

Taking the mean of the results, and reducing the French into English weights, it therefore appears that a turtle dove, weighing 2886·9 grains or 6 oz. troy, consumes in the course of respiration, during twenty-four hours, 78·733 grains of carbon ; and emits, in the same space of time, 288·690 grains of carbonic acid, and 1·470 grain of azote ; or, estimating the quantities by volume, 16·616 pints of carbonic acid, and 0·221 of a pint of azote ; whence it results that the azote exhaled by the animal is nearly the 100th of the volume of the carbonic acid produced,—a

conclusion which agrees, in so far as the fact of the exhalation of the azote is concerned, with that obtained by Dulong and Despretz ; but which differs notably in regard to the quantity ; the azote exhaled, when contrasted with the carbonic acid gas, being much smaller in amount than it was found by these inquirers. Small as the quantity of azote is, however, it still constitutes one-third of that which entered into the composition of the food consumed by the turtle dove. In the circumstances in which this bird was placed, the excrements did not

contain more than two-thirds of the azote which preexisted in the millet seed consumed. Thus, independently of the modifications which the food, or rather the blood which proceeds from it, undergoes in the course of the pulmonary combustion, it may be conceived that a part of the azotised principles of the animal organism also undergoes complete combustion, so as to give rise to carbonic acid, to water, and azote; unless, indeed, we suppose that, under certain influences, the azote of the quaternary compounds may be partially eliminated; and give rise, by this elimination, to ternary compounds.

From the table which gives the elements of the two series of experiments, it is seen that the hydrogen and the oxygen eliminated are not in the proportions necessary to constitute water. The oxygen dissipated in a day being 72·404 grains, would require 9·818 grains of hydrogen to turn it into water. The excess of hydrogen, therefore, which, like the carbon, is burned by the concurrence of the oxygen of the air, is 1·080 grains.

In viewing respiration as a kind of combustion, the preceding data would imply that a turtle dove weighing 6·014 ounces troy, breathing freely in an atmosphere of from 46°·4 to 50° F. (8° to 10° C.) in which it burns, in the course of twenty-four hours, 78·733 grains of carbon and 1·080 grain of hydrogen, may disengage enough of heat to maintain its body at a nearly constant temperature of between 105°·8 F. and 107°·6 F. (41° and 42° Cent.), turning the water at the same time into vapour, which is escaping by the pulmonic and cutaneous exhalation; water, the quantity of which, as will immediately be seen, amounts to more than 46·314 grains troy.

In a first experiment, the turtle dove, on its diet of millet seed, drank, in two days, 197·606 grains troy of distilled water.

In another experiment, 196·652 grains in four days; consequently 394·258 grains, or 98·564 grains, per diem.

It is now possible to make an approximation to the quantity of water which the bird lost by cutaneous and pulmonic exhalation:—

In 12 days the turtle dove, with the millet seed which it ate,	Grains.
took in of water	421·457
Of water it drank directly . . .	1181·007
Whole water consumed	1602·464
Water contained in the 100·29 grammes of moist excrement } grammes of moist excrement }	1099·031
Difference, or whole water thrown off by the pulmonic and cutaneous exhalations }	503·433

Per diem	42·045
Water formed in a day by the } 0·07 of hydrogen in excess }	9·725
Whole quantity of water thrown off in 24 hours by transpiration, pulmonic and cutaneous }	51·871

Medicine and the Collateral Sciences.

FRIDAY, DECEMBER 27, 1844.

CLINICAL LECTURES IN SURGERY.

Delivered at the Middlesex Hospital,

BY MR. ARNOTT.

December 5th, 1844.

THE lecturer began by remarking that as the Council of the College of Surgeons now required of candidates for the Fellowship—and he hoped all those present would wish to become fellows—that they should produce certificates of having attended two courses of clinical lectures in surgery of six months' duration each, it became necessary that these lectures should be commenced forthwith. It was no doubt true, that the most valuable part of clinical instruction was that which was given at the bed-side; but still their meeting in the theatre was useful. Besides observing the daily progress of cases, it enabled him to take a review of some of the cases from their commencement to their termination; it gave him the opportunity of bringing together cases of similar kind which had been at the same time in the house, and of comparing or contrasting them, and of making the pupils acquainted with occurrences which had taken place during their absence, or which they could not have had an opportunity of witnessing. It was not his intention, in these lectures, to read over the daily reports of the cases—these were to be found in the books—but in giving a general account of a case, to dwell especially upon those points in regard to symptoms, course, action of remedies, or appearances observed after death, which seemed most striking, or worthy of being impressed upon their memory. The principal subject of to-day's lecture would be Abscess,—to several examples of which he would now proceed to refer.

Abscess of the Abdomen.

Mary M., æt. 24, married, was admitted 891. 7 XXXV.

Oct. 8th, 1844, with a large abscess on the left side of the abdomen, close to the inner side of the anterior part of the crest of the ilium and the adjoining portion of Poupart's ligament: the integuments over it were red, and examination gave pain; there was no febrile disturbance; looked healthy. Ten days previously had some severe rigors, and three days afterwards first perceived the swelling; at this time, was under the care of the physician as an out-patient, on account of pain in the loins and stoppage of menstruation.

Abscesses in the situation here indicated derive their chief importance from the circumstance of being often connected with disease of the deeper seated parts; and the first question that presented itself in this case was, whether it was consequent upon any disease of the abdominal viscera, was dependent on diseased bone, or was connected in any way with her confinement, which had taken place some months previously. The latter was her own notion; but although abscesses originating in inflammation following labour occasionally make their way here from the pelvis, there seemed no sufficient evidence that the present case was one of that description. There had been no symptoms indicative of ulceration or obstruction of the intestinal canal, or any affection of the kidney. The pain in the loins, and some difficulty which she had experienced in stooping, created suspicion that there might be disease of the spinal column, but careful examination detected nothing confirmatory of this; and although all apprehension on this head was not thereby removed, yet there were other circumstances encouraging the hope that the abscess might not be connected with diseased bone. In cases of the latter kind the swelling usually forms slowly, and the integuments over it long retain their natural colour and temperature; in fact, the abscess is of a chronic character. Here, the case was different; only a week had elapsed from the first detection of the swelling and the

occurrence of those appearances which it presented on the patient's entrance.

It was determined to treat it as an acute abscess, and two days after admission a free incision was made into it, not towards Poupart's ligament, the lowest parts in the upright position of the body, but close to the crest of the ilium, in the situation which would be the most dependent as the patient lay in bed, or which, by placing a pillow under the buttocks, could easily be made so. The matter discharged was rather thin, and as it evidently came from a deep situation, I was not free from apprehension that we should have inflammation of the cyst of the abscess, so often occurring in chronic and symptomatic abscesses, and occasioning the most severe symptoms and fatal results. Fortunately our fears were not realized; no constitutional disturbance took place. Yet the discharge continued copious for some time, and meat, beer, and tonics, were required. A fortnight after the collection had been opened, the probe introduced passed downwards and inwards in the direction of the pubis, above and parallel to the upper part of Poupart's ligament. With the view of aiding to the closure of the cyst of the abscess in this situation, pressure was applied by means of the pad of a truss; but this could not be borne. Slitting up the parts in the direction mentioned was considered, but as this would have entailed a division of the muscles under which the probe passed, it was not deemed prudent thus to weaken the resistance of the abdominal parietes. The opening already made was therefore kept carefully free—the patient was so placed as to keep this almost invariably in the most dependent position; and pressure by the hand was made twice daily on the surrounding parts, in order further to obviate the risk of bagging. Under these means, and the regimen adopted, the discharge gradually abated, so that in six weeks it had entirely ceased, and the wound cicatrised. The patient then got up, but was kept ten days longer in the house, when she was discharged free from complaint. The case may be viewed as one of acute abscess.

The next case I have to notice is one of

Abscess of the Labium Pudendi.

Clara J., æt. 26, married: admitted Oct. 29, 1844. A collection of matter occupied the posterior part of the right labium, projecting on its inner surface and obstructing the entrance of the vagina. Soon after marriage, and when she became pregnant, an abscess formed in this situation, was opened by a surgeon, and it healed soon afterwards. When she had quickened it again collected, burst of itself and closed. It formed a third

time during her pregnancy, and was again opened by her surgeon, and it healed a month previous to her confinement, about eight months since. She suffered great pain in the parts whilst she suckled, but no swelling was observed again until about two months ago.

An examination was made so as to ascertain, if possible, by the finger in the vagina, if any hardness, tract, or sinus existed, leading upwards by the side of this passage, but none could be detected. It was probable, therefore, that the repeated collection of matter in the same place might have arisen from the cyst of the abscess never having healed from the bottom. A very free incision was therefore made into it; and no sinus running from it having been discovered by the probe, lint was introduced into it, and renewed, so as to secure the healing from the bottom, which was effected in a fortnight.

Abscess of the Side.

Wm. Johnson, æt. 32, admitted Nov. 19th, 1844. There was a large swelling, with fluctuation, occupying a space the size of the extended hand on the right side, a little under the axilla. The integuments covering it were red from the effects of a blister applied a week previously. At that time he asserts there was no swelling, which only appeared three days after. The blister was applied on account of severe pain in the part, which commenced a fortnight before, which pain was preceded by three severe rigors, each followed by heat and sweating. Examination of the part could scarcely be borne from the severity of the pain. He looked pallid, his face was flushed, his skin hot, and pulse frequent. He was thirsty, the tongue was covered with a thick yellowish creamy fur, his appetite was gone, and the bowels were purged. The cavity of the chest, and its contents on this side, appeared to be sound. There was no appearance of disease of the spine.

In the absence of all evident cause for this abscess, for undoubtedly it had preceded the application of the blister, my mind recurred, from its unfortunate termination, to the last case of extensive abscess, in nearly the same situation which I had observed. This was in the spring of the present year, in a fine young Irishwoman, who came into the hospital expressly to get rid of what she supposed was a large tumor, which had been growing for the last twelve months. But although the skin covering it was pale, and of not more than the natural temperature, and although it was quite free from pain, yet fluctuation was present in it throughout. It was an abscess, but no cause could be discovered for it in the neighbouring parts, external or internal. It was freely opened, and a large

quantity of serous pus evacuated. Considerable constitutional disturbance succeeded; fever, and pain in the side, with cough, but these yielded to leeches and salines, and, with the exception of the discharge, matters had greatly improved, when, a fortnight afterwards, severe symptoms of inflammation of the same side of the chest, bronchitis, and pneumonia, supervened: under these the patient sunk six weeks from her admission.

On examination *post-mortem* the cause of this *chronic abscess* was discovered to be necrosis of the fifth and seventh ribs, where they are covered by the scapula, from their angles forwards, about two inches of each. This case will afford you additional proof that it is not without reason we look with anxiety at all cases of large abscess of the trunk, especially when chronic and of obscure origin, lest they should be symptomatic; that is, dependent on other and more serious disease.

In the case of our present patient, Johnson, although apparently one of *acute abscess*, you will recollect that my anxiety led me, notwithstanding, to introduce my finger into the opening which I had made to evacuate the matter, to pass it upwards to its full length towards the axilla, backwards to the scapula and all over the ribs, so as to satisfy myself that there was nothing more present than the irregular surface of an acute abscess. The febrile symptoms and constitutional disturbance now subsided, and under simple remedies, mild aperients and salines, the discharge, at first copious, gradually abated, and in a fortnight it had entirely ceased, and the opening healed. Three weeks from his entrance the patient was discharged well.

I have just now alluded to diseased bone as a cause of abscess. The case to which I shall next refer possesses a two-fold interest, as exhibiting the condition of the hip-joint after being the seat of continued disease for fifteen years, and giving occasion to frequent abscesses, but more particularly from its having afforded you an opportunity of witnessing an instance of death arising from suppression of the secretion of urine, and of observing the mode in which this fatal result ensues from the retention of the urea in the system, and its action upon the brain.

Disease of the hip—Complete suppression of Urine.—Coma—Epilepsy—Death. Urea present in the serum contained in the ventricles of the brain.

Ann Lovegrove, æt. 24, was admitted Oct. 29, on account of severe pain in the left hip. There had been disease of the joint since the age of nine, abscesses from time to time forming, discharging and slowly heal-

ing. There were now two sinuses in front of the joint, which had existed for two years. Pressure on the trochanter greatly aggravated the pain already existing, and there was a *dematous swelling* of the soft parts in this situation. The thigh was considerably flexed on the pelvis, and fixed thereon, the slightest motion not being perceivable in the joint. Until within the last six months she did not suffer much pain in the hip, but up to this time she had used a crutch. She then adopted a high-heeled and thick-soled shoe, and she attributed the pain since experienced to the greater use of the limb consequent upon the adoption of the shoe, and the rejection of the crutch. She had had diarrhoea, with purging of blood, for the last nine days; tongue very red.

Great difficulty was experienced in moderating the diarrhoea, the medicines for a time succeeding, and then losing their effect; this was the case with the combination of Dover's powder and Hydrargyrum c. Creta; with the chalk mixture, &c.: the most efficient means were found to be the occasional injection per anum of laudanum and starch, and lime-water taken by the mouth. It was hoped that rest and fomentation would suffice to relieve the pain in the hip; but not so: its permanence and severity preventing sleep, led to the application of a caustic issue behind the trochanter, which afforded immediate and durable relief.

You will recollect that I repeatedly pointed your attention to the state of the patient auguring unfavourably, from the pertinacity of the diarrhoea, and the red tongue. But on Tuesday, the 28th of Nov., just a month from her entrance, you will remember that I particularly directed your attention to a new phasis in her case: the preceding day I noticed that she was slightly drowsy, but this was now more marked; and you will remember how, that in rousing herself to our questions, she opened her eyes, and turned her head, exactly like a person awaking from a very deep sleep—that she answered slowly and listlessly, that her pupils were dilated, and that she had a very vacant expression of countenance. Her hands were cold, and very slightly oedematous; there was no pulse to be felt at the wrist. On the previous day I had ascertained upon inquiry that very little water was made, and on passing the catheter only a teaspoonful was obtained, then eighteen hours afterwards; but a table-spoonful was contained in, and withdrawn from, the bladder. On exposure to heat, three-fourths, perhaps seven-eighths of this, was converted into coagulated albumen.

The cause of the head symptoms was clearly the arrest of the secretion of urine; but how was this to be restored? It was proposed to

give Tinctura Lyttæ, but the very red tongue was thought to render this inexpedient; the *Haustus Terebinthinæ* was given in its stead, and a mustard poultice placed across the loins. The state of the circulation forbade more active treatment directly to the head, but it was shaved, and a blister applied.

By the evening of the same day, (*viz.* the 28th) the patient no longer replied to questions, she could not be roused, the stupor amounted to coma, and the pupils were observed to be contracted to a point. On the morning of the 29th, she had an epileptic fit, another in the middle of the day, when the breathing was found slightly stertorous, with puffing out of the cheeks; she had four or five more fits before she expired in one of these at four in the morning of the 30th. No urine was secreted during the last forty hours.

On examination, the head of the femur and acetabulum were found ankylosed externally all round, the neck of the former bone having undergone considerable diminution of its length, but the consolidation of the two bones was so complete that it is in possible, as you may see, to determine the precise limits of each. A portion of the osseous uniting medium is bare. On making a section through the acetabulum and neck of the femur, in the direction of the latter, the osseous ankylosis, though complete, and of solid bone externally, so that it is impossible to say what is femur and what acetabulum, is, as you will observe, somewhat defective in the centre. Here, in a situation corresponding, as it were, to the centre of the joint, we find a cavity in which is lodged a piece of dead and loose bone. From this cavity, you observe, we can trace a narrow passage through the surrounding uniting bone in the front part of the joint, a sort of cloaca we may call it, and presenting a state of disease sufficiently accounting for the long continuance of sinuses in this situation, and the persistence of the other symptoms of hip disease.

The kidneys were rather above the natural size. On stripping off their investing coat, they presented a mottled appearance, and tuberculated surface; the colour of these tubercles, which are very numerous and agglomerated, being, as you observe, of a dirty yellow, or straw colour. On a section being made, this colour was found to occupy almost the entire of the cortical, or secreting part of the organ, which thus presented a well-marked instance of what is called Bright's kidney. There is a cyst in one of them, which is common enough. Usually in this form of disease the surface of the kidney is granular; here it is not so, but tuberculated; but this we may probably attribute to the more advanced stage of the disease. In confirmation of this, I may state

that I learn from our apothecary, Mr. Corfe, that this young woman was in the physicians' ward a year and half ago, when she had incontinence of urine, and the urine was albuminous, the disease no doubt then existing.

The bladder contained no urine, it was quite contracted, its coats were somewhat softened. On opening the head, there was but little serum in the arachnoid; on slicing the brain, the red points were unusually numerous; about two ounces of serum were found in the ventricles.

Urea has been detected in the serum of the blood of those labouring under albuminuria, and suppression of urine, by Christison, and others, and the same substance has been found in the serum secreted into the ventricles of the brain. But this was deemed too good an opportunity of confirming this, not to take advantage of the able assistance of Mr. Fownes, our lecturer on chemistry, for this purpose. Accordingly a portion of the serum contained in the ventricles of the brain was handed to him, in which he readily discovered the presence of urea. His manner of proceeding was this, he informs me. He first got rid of the albumen which was present in the serum in large quantity, by boiling, filtering, and evaporating to dryness; he then applied a little water to the residuum, and adding some nitric acid to it in a watch glass, it was allowed to stand over night, and in the morning he found crystals of nitrate of urea.

The urea retained in the blood seems to act as a poison in these cases, and although, when these effects ensue, we do not well know how to counteract them, yet having had so striking and well-marked an example of the symptoms which it produced, you will at least be prepared, should a similar case occur to you, to forewarn the patient's friends of his or her danger, and thereby tend to preserve your own character.

In this case of Bright's kidney there was no dropsy. The diarrhoea which existed was probably, however, dependent in its origin on the renal disease.

INFLUENCE OF THE NERVES ON SECRETION.

To the Editor of the Medical Gazette.

SIR,

WHEN a series of phenomena have been traced up to an ultimate fact, as those of fever up to the irritability of the blood-vessels, and the inferences arising from it have been applied and fully carried out into practice, the subject is complete, and very little can be added

to it; because so long as the ultimate fact remains established, as we cannot go higher than or beyond it, no farther extension of principle can be obtained, and, consequently, no great or comprehensive improvement can be made, and not much even in matters of arrangement and detail. It seems to me that the theory and practice of medicine are in this condition at the present time, that all the practical benefit to be derived from cultivating the science of medicine (i. e. what is now called science) has been obtained, the soil is exhausted, and consequently the labour now is great, the profit very small. Thus we find one author as the result of a long investigation, discovers inflammation to consist in "*a peculiar perversion of nutrition or secretion*;" another spends years in examining the blood, as if disease could be cured by putting into the stomach this or that ingredient, which he might find deficient. Another revives and produces as a novelty, the doctrine of vibrations; a fourth publishes a series of drawings of morbid growths and depositions, as if the contemplation of them would throw a new light upon the cause of production. Seeing that in all these instances, and in many more which might be mentioned, the labour of able men is so great, and the gain so small, we might conclude that nothing more could be done, did not the unsatisfactory state of the *practice* of medicine prevent the possibility of our being contented with it.

I have long been convinced that the true reason why so much patience and zeal have of late years been expended to so little purpose, is, because the present doctrines being founded on a *supposed* ultimate fact, have not admitted of any extension of principle, and I have been sustained with the expectation of my labours being crowned with happier success by observing, that in tracing the contraction of the muscular fibre, and the maintenance of the secernent function up to the nervous system, thus getting beyond the ultimate facts, we might advance a step higher in the gradation of causes, and obtain the requisite extension of principle. The controversy respecting the doctrines of irritability may be likened to the letter Y, the two extremes of which, though wide apart, at first gradually approach each other, and

unite in a single stem; so the two parties to this dispute, however at variance in their principles, concur at length in adopting the same practical views. It seems to me that this diversity at the commencement, and unanimity at the conclusion, have had the effect of confining the interest of the question entirely to those engaged in carrying on the discussion, because the great mass of the profession being practical men, have naturally looked to that part of it which more particularly concerned them, and finding the same treatment recommended by each party, have considered it a matter of perfect indifference which might be in the right. Indeed, I am inclined to believe that although systematic writers have been obliged to keep their doctrines connected, and as much as possible consistent, each practical man has deemed himself at liberty to form his own physio-pathological creed, and that this in most instances is a strange mixture of the leading points of each side of the controversy. I should never have troubled myself, however, to interfere with this anomalous state of things, had I not hoped, by showing what may be gained by an extension of principle, and by bringing it to bear legitimately in improving the treatment of disease, to excite a permanent and abiding interest in physiological questions in the minds of practical men.

The first great fact on which I wish to fix the attention of the profession is that which I brought forward in my last letter, viz. that the body cannot live without the brain. The second is very similar to it, viz. that when the communication of a *part* with the brain is completely cut off, it also dies. There is a completeness in the entire separation of a part from its nervous connexion with the brain, which does not belong to the division of one or more branches only; the one gives a perfect, and the other only an imperfect result; if we can understand the first, there will be no difficulty with the second. It is observed that inflammation and disorganization invariably intervene between the division of the nerves, and the final death of the part supplied by them. Analogous phenomena are remarked in some of the severer forms of rapid disease, where fever and disorganization intervene between the health and death of the whole body;

hence the application of the term putrid to some of the graver kinds of fever. Now it is quite certain the inflammation in the part is caused by the division of its nerves, and consequently it is fair to infer that some cause or other acts in an analogous manner upon the whole nervous system in producing fever; and as all disease may be ultimately resolved into the question of a greater or less degree of inflammation, or of fever (as I have already said on a former occasion, when endeavouring to show how absolutely necessary it was to establish sound doctrines on these points in a cyclopædia or dictionary of practical medicine), it becomes morally certain that there is no way of arriving at a deeper insight into disease except through a more perfect knowledge of the functions of the nervous system. From what has been said, it follows that the one thing needful is such an amount of information respecting the office of the brain and nerves in maintaining life or health as shall enable us to understand what amount of injury is inflicted on a part by the division of the latter, what it loses, in short, by its communication with the brain being interrupted. The only functions of the nerves which have as yet been investigated with success are those relating to volition and sensation; and many have appeared to think that these points being ascertained no farther information was necessary. It seems to me, however, that a little reflection on the nature of these properties, considered in connection with the actual arrangements and distributions of the various nerves to the several parts and organs of the body, and the fact that a part dies when all its nerves are divided, discovers a great void still remaining to be filled up. Nerves of sensation are invariably united (except those of the special senses) either with nerves of volition, with ganglial nerves, or with both. Wherefore do we find this constant union of different kinds of nerves? Volition and sensation are properties entirely distinct from, and independent of, each other; consequently these functions would be quite as well provided for by nerves having no intercommunication. No consideration, therefore, of properties distinct, and even opposed to each other, can possibly lead to an explanation of the

reason why nerves endowed with them should be so constantly united. But if the more obvious and acknowledged functions of the nerves are such that their union is not required on that account, may there not be some other function as distinct from volition and sensation as they are from each other, and yet not incompatible with them, which imperatively demands and cannot be carried on without such a disposition? These questions refer us back to the consideration of the facts before us; and here, when we see not only muscles, but bones, ligaments, and joints—parts neither capable of moving, nor, under ordinary circumstances, very sensitive—supplied by anterior and posterior nerves, and perceive also that muscles, bones, and ligaments, all become disorganized and die together when the nerves are divided, we can scarcely avoid the conclusion that the nerves do subserve another function, and that in all probability it is the performance of this other function which renders it necessary for the nerves to be united as we find them. An author who occupies a conspicuous position among the writers of the present day maintains the opinion, that the secret function is independent of the nervous system, although liable to be influenced through it. It would be difficult to recognize even a trace of the wise beneficence of our great Creator in such a disposition as this doctrine implies, because since all mental emotions interfere with and interrupt secretion, and may even be so intense as to kill instantaneously, the influence is only exercised for evil, which would be a solicism not to be found in any other part of the creation. According to this view, either Dr. Alison is wrong, or God has in this instance departed from his universal law. If such be the tendency of the doctrines taught by one of the best authorities of the present day, there can be no doubt but that a good work on physiology has yet to be written. Physiologists have never yet considered more than half, and that the least important half, of the functions of the nervous system; their attention has hitherto been almost solely fixed and concentrated upon volition and sensation, functions which relate only to the convenience of the body, as if the whole subject were comprised in them :

these are doubtless important functions, but that which maintains the life is unquestionably of far higher consequence; and yet no one knows any thing about it. I was in hopes I should have been able to enter upon the question of the secret function of the nervous system in this letter, but I find I must defer it to a future opportunity.

I have the honour to be, sir,
Your obedient servant,
J. W. EARLE.

Cheltenham, Dec. 3, 1844.

ON THE PRESENT STATE OF THERAPEUTICAL INQUIRY.

BY JAMES ARNOTT, M.D.
Physician to the Brighton Dispensary.
(*For the London Medical Gazette.*)

IT is remarkable, that the branch of the science of medicine which has regard to the cure of disease, and which is obviously its most important branch, should, at the present time, be the most neglected. Amongst the various causes which may be assigned for this neglect, the principal is the extreme difficulty of establishing any improvement in medical practice, or even of drawing the attention of the profession to it, and inducing them to make a trial of the newly proposed treatment. The proposer of this finds that his assertions are received with incredulity; and his new remedy is either not tried at all, or is tried so imperfectly as to throw discredit on his judgment, if not on his veracity. Unless he be one of those whom accident has placed in charge of a large public medical charity, and who have consequently many professional witnesses of their proceedings; or unless from other circumstances equally accidental, and often quite independently of his merits, he has become what has been termed an authority: this neglect will surely be the fate of his improvements, excepting, perhaps, such of them as are founded upon physical principles of easy comprehension, or which promise relief in diseases for which no remedy of any kind has hitherto been found.

The microscopical and pathological anatomist, the investigator of animal chemistry, and the physiologist, are

very differently situated in respect to the reception of the result of their labours by the public. They can produce demonstrable, undeniable, facts in proof of their assertions; and they are cheered in the prosecution of their respective studies by the acknowledgment of the advances which they have made in science.

Amongst the causes of the unpopularity of therapeutical investigations, the perfection to which this department has attained, and the scanty harvest of discovery that can consequently be hoped from its cultivation, cannot assuredly be reckoned. On the contrary, of all the branches of medical science, therapeutics is the least advanced. How few diseases are there, upon the best mode of treating which, medical men, not only of various countries, but of the same country, have generally agreed! How many for which it has been generally acknowledged that no remedy has hitherto been discovered!

Inflammation is the proximate cause of the greater number of acute and severe diseases, or the cause at least of the dangerous local affections occurring in the course of these; and of no morbid condition is the remedial treatment supposed to be better known, or more certainly fixed; yet even here how various are medical opinions about the proper means to be adopted, and the degree to which they ought severally to be carried!

Blood-letting is the principal remedy of inflammation. But its advantage has been questioned by the most accurate observer of the day, M. Louis, even in pneumonia; although pneumonia and venesection are the very disease and remedy which have usually been mentioned together as the best evidence than can be adduced of the efficacy of the healing art. Few will be found of the same opinion with M. Louis on this point; yet as a proof of how little is yet known of the proper extent to which the abstraction of blood should be carried, and of the proper manner in which it ought to be made, in this and other equally severe inflammatory diseases, it still remains the usual practice of physicians to prescribe a determinate quantity to be drawn, without observing the effects of the operation until after a considerable period has elapsed; notwithstanding the general admission that the effect of

blood-letting is very materially influenced by the mode in which it happens to be performed, or the manner in which the blood happens to flow from the vein. In former times, the observation of the immediate effects of venesection was deemed of more importance than the quantity drawn; and Sydenham mentions with approbation, the practice of a surgeon in his day, who allowed the patient's blood to flow upon the ground, while he exclusively watched the effects of its loss on the system.

Some improvement, I think, may be made, with this view, in the operation of venesection. If the bandage by which the veins are compressed were tightened or loosened by a small tourniquet screw, the force of the stream of blood might be regulated with almost as much ease and precision as that of a jet of water is regulated by a stop-cock. Although this addition renders the *apparatus* used a little more complex, it simplifies the *operation*.

Blisters, as a remedy of acute inflammation of the viscera, are condemned by many, as being more calculated to aggravate than relieve; with others they form a part of their invariable routine.

Purgatives constitute a principal part of the treatment of febrile and inflammatory disease in this country; in France they are generally regarded as the pernicious irritants of the gastrointestinal mucous membrane.

Emetic tartar is rarely employed by English practitioners in repeated large doses, so as to act as a sedative on the system. In Italy it is a substitute for the lancet.

Cold applied externally constitutes with some an important part of the treatment of inflammation, particularly when affecting the head, joints, or external parts; and it has occasionally been extended to similar affections of the throat, chest, and abdomen. Other practitioners consider it more likely to cause injurious determination to the morbid part than to relieve its oppressed vessels. Much of this discrepancy, however, has, doubtless, arisen from the very imperfect mode (as will be explained in a subsequent section) in which cold has hitherto been applied. If cold, instead of being constantly applied, is applied by intervals, it is more likely to stimulate by reaction, and really to increase the

temperature, than produce the contrary effects.

Still more undecided than any of the above opinions is that on the constitutional effect of mercury as a remedy of inflammation. This powerful drug, the extensive use of which as a remedy for acute inflammation as well as fever originated in our eastern colonies (but where it now appears to be estimated as much below its real value as it was formerly above it) is deemed by many not to be inferior in efficacy to bleeding, when employed in sufficient quantity. A very different opinion is entertained upon the subject by others. The distinguished professor of the practice of medicine in the University of Edinburgh, for instance, declares that he has seen "the symptoms of inflammatory diseases more frequently aggravated or transferred to another part, on the mouth becoming affected with mercury, than relieved."* Although this extreme opinion may be classed, on account of its singularity, with that of M. Louis on bleeding in pneumonia, it must still be admitted that many practitioners continue to participate in the vulgar prejudice against mercury; and the mode of administering the remedy in urgent cases still remains very imperfect. The necessity that is admitted for the speedy application of other remedies, or rather for the speedy production of their respective influences, can scarcely be supposed to be the case with respect to the use of mercury, when we daily witness patients sinking under diseases for which the practitioner is administering mercury, with the full expectation that its complete action would save, and yet administering it in a way the least likely to effect its complete action speedily, and in time to save. However weakened or torpid the power of absorption may be in the stomach and upper part of the intestinal tube, it is rarely that mercury is exhibited otherwise than by the mouth, or by friction on the skin. It is more than twenty years since I induced mercurial salivation, where there was no hope of succeeding in this from the usual, and perhaps milder methods, by applying lint soaked in a solution of the bi-

* The Library of Medicine, vol. i. p. 111.

chloride of mercury to a portion of the skin from which the cuticle had been removed by a blister. This is not the only mode in which the system may be speedily affected by mercury, in cases where the urgency of circumstances authorises the use of severe remedies; and that these modes should have been so completely neglected, can only be accounted for by supposing that erroneous notions upon the *modus operandi* of mercury have prevented their use. By introducing the drug into the system more gradually, a more general effect has been supposed to be produced; upon which general effect exclusively the remedial efficacy has been thought to depend.

The above observations have reference to the general treatment of a large, and by far the most important class of diseases: if particular diseases be considered, the present state of therapeutics will not appear to greater advantage.

Take rheumatism for an example—the most common disease of a severe character which we have to treat in this country, and consequently one on the management of which, it might be supposed, there would be little difference of opinion. There are at least half a dozen very different modes in use of treating cases of rheumatism, of precisely the same character. One practitioner, considering the disease to be purely inflammatory, trusts principally to the lancet, employing or eschewing mercury, according to his notions of it as a remedy of inflammation. Another confides exclusively in powerful diaphoretics. Those who acknowledge a specific virtue in colchicum require little other assistance; while others, with Dr. Haygarth, fancy they find an equally powerful specific in bark. Opium and nitre have each their respective advocates as the sheet-anchor to be relied upon. And while certain practitioners of the eclectic school variously combine the above remedies, or appropriate them to what they consider suitable cases, a few expectants, or homœopathists, (for there is no great difference between these sects,) may be found, who leave the cure to the unaided or unopposed operations of nature.

Although it may be deemed a departure from the subject of therapeutics,

yet as bearing immediately upon it, and strongly influencing it, there may be no great impropriety in briefly advertent to the great uncertainty that exists respecting the *modus operandi* of remedies; and in bringing forward as an illustration of this, the various opinions that are held on the action of mercury, the last mentioned of the principal remedies used in inflammatory disease. In the opinion of some, mercury given to the extent of affecting the system acts beneficially, by stimulating the absorbents; another explanation is, that it equalizes the circulation, or restores its balance. Some think that its curative agency consists in the general excitement of the secretions, or in other words, in being a general evacuant; and there are still a few who deem its action advantageous by destroying the poison from which the disease originated, or by ejecting it from the mass of circulating fluid. Many conceive that mercury removes the morbid action constituting disease, by exciting another action, which supercedes it, on the principle that two morbid actions of different kinds cannot co-exist; and others adopt the similar idea that a general counter-irritation is produced by its powerful and diffused action operating beneficially in causing a revulsion from the morbid part. It is to be regretted that an explanation which has lately been advanced, namely, that it dissolves the blood, did not occur to Boerhaave, or his disciples, as by ensuring its general adoption, from its applicability to the reigning doctrines in pathology, it would not only have led to an earlier and general use of a valuable medicine, but long ere now, and as the fruit of so extended an experience, some certain principles regulating its use would have been arrived at. Many years ago, and when I had ample opportunity of witnessing the extraordinary effect of severe mercurial ptyalism, (sometimes where there is constitutional peculiarity, produced by a few grains of mercury,) in quickly putting a stop to the symptoms of the acute and rapid diseases of warm climates, I was led to the conclusion, that while it might have several other operations of an auxiliary character, its local effect on the mouth and salivary glands was mainly instrumental in effecting the

cure, on the common, and universally admitted principle of counter-irritation. For none of the means commonly used to produce counter-irritation or revulsion, as blisters, &c., are half so violent, or half so continued in their operation, as the degree of mercurial pytalism alluded to; nor as regards their locality, can any of these be so well applied to control the centre of the nervous system, or the gastro pulmonary mucous membrane. Would it not, therefore, be a strange anomaly, if a counter-irritation so powerful, so continued, and so happily situated, should not have, not only the efficacy of other counter irritants, but an efficacy much greater, and in some degree proportionate to these advantages over them? If there be any truth in this view of the subject, we should be led to expect some advantage, similar to that proceeding from this operation of mercury, from exciting a severe and continued irritation in the same situation by more direct, and, in other respects, less noxious measures; and from my observations on this point, I have seen abundance of reason to regret, not that the direct sialagogues hitherto employed have become obsolete in the practice of medicine, for their practice was too mild to be of much service, but that articles of similar, but much stronger local operation, should not have been used as their substitutes.*

* In questions of medical jurisprudence the subject of the certainty of medicine comes prominently before the public; and it has ever been a favourite expedient of the prisoner's counsel to invalidate any medical evidence against him, by exposing the difference of medical opinion upon the points at issue. For the sake of the character of therapeutics, therefore, it was fortunate that in the late remarkable trial of Belaney for the murder of his wife, there chanced to be so much unanimity displayed respecting the remedies which ought to have been adopted as antidotes to the poison which she had taken; but I cannot help saying that it was strange, considering the great importance of the opinions on this point in the particular case referred to, that they should have been so decidedly expressed.

It is doubtful, in the first place, whether the antidotes which have been found effectual in the case of the poisoning of animals would be equally so when administered to the human subject; and the statement made by one of the medical witnesses to the effect, that the practice which ought to be pursued in cases of poisoning by prussic acid is well established and universally taught, I do not think quite correct. In the popular French class-book, for example, the "*Elémens de Pathologie*," by MM. Roche and Sanson, published ten years ago, no allusion is made to any of the remedies (and they were four in number) which the medical witnesses at the trial spoke of as being so effectual!—*Nouveau Elémens de Pathologie*, troisième édition, vol. v. p. 689.

Enough has been said in proof of the very defective state of therapeutics. But when such deplorable uncertainty exists respecting the treatment of the most important class of diseases, and the mode of action of the most important of our remedies, should the attention of the promoters of medical science be so exclusively directed, as it is at present, to its auxiliary or collateral branches?

Among these, none deserves a higher place than morbid anatomy; and great have been the advantages derived from the ardent prosecution of it during the last thirty years. The existence of diseases has thus been ascertained, which, from the similarity of their symptoms to those of other diseases, might never otherwise have been detected; and analogies in the nature of diseases previously supposed (judging from their symptoms alone) to be of a different character, have been discovered, leading to analogies in their treatment; or to the adoption of remedies for certain diseases which experience had proved to be useful in diseases to which they have thus been found allied. Our knowledge of the symptoms of disease has been advanced from the same cause. Aware of the existence of the different diseases, we have been taught to examine the morbid indications more closely in order to discriminate their characteristic symptoms. It was probably in consequence of Laennec's pathological investigations into diseases of the chest that he was led to invent the admirable mode of detecting them by auscultation*.

* Auscultation, though seldom fallacious in its intimations, may, if too much relied upon and other symptoms be neglected, lead into error by its silence—it may deceive, not by misstatement, but by concealing the truth. I was lately called to see a boy in an advanced stage of pneumonia, in whom, during the last four days of his life, no sign was perceptible on the most careful auscultation excepting a slight dullness on percussion at the lower part of the right lung. Not even the natural respiratory murmur was heard. On examination, post-mortem, nearly a fourth part of the right lung was found hepatized, and the various other preliminary changes were perceptible in other portions. It would seem that the uneasiness caused by inspiration prevented the patient from inhaling a sufficient quantity of air to elicit the ordinary sounds. But even here, the very absence of the usual respiratory murmur was a negative sign of some importance; and had the child been compelled to make a full inspiration by obstructing his breathing for a moment or two, the usual declaration of disease by abnormal sounds would probably have been made. In this case, fortunately, the general symptoms were too well marked to endanger error in the diagnosis.

Yet it cannot be denied, that while, on the one hand, many zealous pathologists, in tracing with so much care the marks which disease has left on the animal structure, appear almost to have forgotten that their labours are only useful as subsidiary to therapeutics; on the other hand, error has been committed by a too hasty application of supposed pathological discoveries to medical practice. Sir Benjamin Brodie, for example, observing in his dissection of diseased joints that the synovial membrane presents, in many instances, an appearance different from what is usual after chronic inflammation, assumes that a peculiar disease has existed in such cases; and concludes, because this disease has not been cured in the individuals whose limbs he had examined after amputation, that it is incurable. On this supposition that the disease is incurable, he advises that attempts should not be persisted in to save the limb at the risk of the patient's general health; notwithstanding his admission of the difficulty of distinguishing this peculiar affection from cases of chronic inflammation accompanied with thickening of the parts, and effusion. The supposed accuracy of diagnosis which, it is boasted, has been lately attained in diseases of the joints, has, I conceive, led to many errors in their treatment. An example may illustrate this more briefly and satisfactorily than any argument. About three years ago, several eminent surgeons were consulted on the case of a little boy, in whom I was much interested, suffering from a chronic and deep-seated disease of the ankle and heel. As might have been expected, from the present state of our knowledge of these affections, there was considerable diversity of treatment recommended; though there was little hope, from the supposed nature of the case, held out of recovery. It was determined, however, to adopt the measures that experience has proved to be useful in inflammation, whether acute or chronic, in parts of analogous structure, and an apparatus was contrived by which these measures might be applied to the joint. By means of a plaster cast of the limb, a light and open metallic cage was constructed, accurately fitted to the leg and foot, but considerably wider than the diseased part, and

opening by hinges, by which, at the same time that the joint was kept immoveable, the appropriate dressings, &c. could be easily applied. While the heat of the part was above the natural standard, indicating the existence of acute or subacute inflammation, the temperature was regulated by surrounding the joint with a bladder, through which a current of cold water was allowed to pass; and afterwards a moderate support was given by equable pressure. The usual measures were adopted to improve the general health as well as to remove the existing strumous diathesis; and in little more than twelve months the perfect use of the joint was restored.

It was, I conceive, to his having made no vain attempts to discriminate between the chronic deep-seated affections of the joints, that Mr. Scott, of Bromley, principally owed his remarkable success in their cure. He treated them all as chronic inflammations, and secured the great requisite in the treatment, namely, perfect quietude, by covering the joints with a mass of plasters and bandages. The great improvement that has taken place in the treatment of these diseases within the last thirty years is mainly to be ascribed to the full and universal adoption of this principle; and in criticising the composition of Mr. Scott's plasters and various medicaments, it must not be forgotten that whatever evil may at times have proceeded from this, and from the retention by the dressings of the morbid heat, it was much overbalanced by their keeping the joints perfectly motionless.

With morbid anatomy, animal chemistry and physiology have made rapid advances: and it cannot be denied that a certain degree of benefit has accrued therefrom to the practice of medicine: but, considering the low state of therapeutics, would it not be well, for those at least who, from their connexion with public institutions, have the requisite opportunity, to lay aside for a while their magnifying and precipitating glasses, and to stop the experimental torture of animals, for the purpose of dedicating their leisure to the investigation of the effect of remedies upon disease? It is true that by the cultivation of the auxiliary sciences, therapeutics will be eventually ad-

vanced, and probably to a material degree; but in the meantime the present generation suffers: and considering how little has hitherto been effected by the theories built on these sciences, we cannot indulge a very sanguine hope of any great advantage from them being speedily attained.

It has indeed been but in a very slight degree to any such theory that the practice of medicine is indebted for whatever progress it has made. A statement of the real sources of what is useful in therapeutics, and an inquiry into the means by which these may be rendered most available for its progress, will constitute the subject of the remaining part of this paper.

[To be continued.]

ON THE
SEAT OF HEADACHE,
AND ITS
IMPORT IN DIAGNOSIS.

By T. WILKINSON KING, F.R.C.S.E.

(For the Medical Gazette.)

Internal Sensibilities. Pains certainly referrible to the skull and its membranes. Not in the brain, except in especial lesions of sensitive nerve-tracts. Distresses referred to the periphery. Conclusions.

THE pains of the interior of the body are less distinctly located than those of the exterior, by reason of the absence in the former of that habitual and correcting experience which the senses in general supply to the latter. We are easily deceived in feeling with parts of the hand in an unusual posture; practice, on the contrary, makes even the foot of an armless child almost as ready with mobility and with tact as the hands should have been.

A boy who died in Guy's Hospital described a pain in the left loin; the disease was found to be inflammation of the right kidney. There was no left kidney, nor other disease near the seat of pain, to substantiate the description.

The viscera of the trunk being only attached behind may afford some reason why so many pains are, too hastily, referred to the back. It is only by trying with the hand that the mind

learns to locate a pain in the side, and this is done but indefinitely.

Running after a meal causes pain in the right or in the left side, but its actual seat would seem always to be near to the cava or the porta, since pressure on either side, or a firm belt, are equally calculated to relieve it. The pain of peritonitis, of pleuritis, of pericarditis, or even of arachnitis, is an accidental attendant, often absent, and bearing no proportion to the state of the serous membranes. It seems to depend on the inflammation of the sensitive tissues situated exteriorly.

The seat of pain in cases of pleuritis may have very peculiar reference to the part inflamed. An abscess in the apex of the lung may involve the first dorsal nerve, and produce great uneasiness towards its distribution. The next lower intercostal nerves, if invaded posteriorly, would affect the back of the axilla; and nerves which come out between the cartilages of the true ribs may seem to be the seat of disease which is really in the larger trunks from which they are derived.

It is a curious instance of false perception that tickling the umbilical pit refers a sensation to the generative organs; but a little experience corrects this erroneous impression, as the part becomes more accustomed by repetition of the experiment.

A lady, about fifty years of age, is subject to depression and to flatulence, and to distressing pain near the angle of the left scapula; the pain is instantly relieved by a sufficiently copious windy eructation.

A young man suffered for months from occasional anxious attacks of sharp pain within the lower ribs on the right side. He was accustomed to sit in his chair, changing his posture with the expectation of rather sudden relief. He died of a different affection. In the pelvis of the right kidney was found an oval stone, the partial roughnesses and polish of which seemed plainly to indicate that it had been liable to pass into the orifice of the ureter and back again, thus explaining the nature of the suffering. The renal pelvis was dilated, but the kidney was as yet scarcely unhealthy. How many sudden nephralgiæ may this assist to explain!

That many organs are hardly sus-

ceptible of sensation or of pain as regards their proper structure, seems a very important fact to be remarked. The heart, lungs, liver, spleen, kidney, and brain, are continually found to have been the seat of almost any kind of disorder without evident suffering. There is no pain when a small intestine is first strangulated, nor when the bowel is handled in operations. A dog is quite insensible of pain when the ileum is pinched and lacerated.

The sensations of the stomach are numerous; those of the cœcum, or at least of the parts on which it lies, are also not doubtful: and a considerable part of the end of the large intestine has its own needful sensations, and which are often even distressing. Mr. Hunter thought that by sensation he could trace the progress of an active purgative through the intestinal canal.

Headache is too common and too variable in many disorders to be very available as a specific sign. Its value of course depends on a right estimation of it, and the indications to be drawn from its absence depend greatly for their utility on a just knowledge of the diseases which may give rise to pain in the head, and on the discrimination of the parts which, when affected, do not give rise to pain*.

Lesions of the dorsal medulla, or of its nerves, induce a considerable variety of deranged feelings, as of motions, numbness, tightness, burnings, sense of coldness of common sensibility declining, or morbidly acute injury, benumbs the lower half of the body, and the upper boundary of the skin so affected aches, or with a little violence seems to burn. Certain tense cords are here oppressed, others are perhaps in a manner inflamed. All this applies with something more of intricacy to the brain itself, and it would be no little service if the various distinct examples that pathology may afford were to be collected. The function of parts, and the uses of symptoms, would admit of fair explanation by such means. It is a striking fact, however, that pains, auras, convulsions, or palsies, in one arm, occur very variously from circumscribed diseases within the opposite side of the brain,

with either head-ache, or mental disturbance.

The study of the affections of distinct parts of brain substance requires but little argument to recommend it; the advantages must follow too plainly to need illustration: my method, however, of pursuing the inquiry, may yet demand some apology.

If head-ache be confined to parts without the arachnoid membrane—if mental disorders depend on no other parts than the convolutions of the cerebrum—if lesions of motion are to be referred only to particular cords, tracts, or radiations in cerebrum and cerebellum—if the like apply to lesions of sense, then doubtless the learner will be glad to find first of all simple and distinct illustrations of these facts, and to meet with some explanation of the confusion, and of the doubt, which more complicated cases throw over the whole inquiry.

The history of strumous tubercles in the cerebrum serves to illustrate the course of signs depending on sensitive, mental, and motor parts. Varying and severe head-ache at intervals indicates vascular disorder, involving the entire head, or greater part of it, much as signs as the eye and face, and other general or distinct symptoms, do;—the solid slough of repeated capillary relapses growing by concentric layers all the while.

If severe disorder spread over the convolution, the mind errs, or mandatory ends of motor tracts being invaded, we have corresponding palsy or convulsions, or both, alternating more or less partially, or all points may be suddenly oppressed.

Tubercle in the brain being attended by the like elsewhere, almost invariably, and also by atrophy in general, seems to be the reason why the brain symptoms are kept back, and perhaps even not developed in the final fatal inflammatory seizure.

Dr. Hennis Green, in a valuable digest (*Med. Ch. Tr.* vol. 25, p. 204,) makes one-third of the cases of cerebral tubercle to commence with signs of disturbance in the centre of the brain only, *i. e.* with convulsions, &c.; but scarcely ever with head-ache, and in such cases, the mental disturbance is only, or chiefly, a final symptom.

Disturbances of motor tracts affect motion, and those of sensitive tracts

* There are of course different kinds of head-ache. That which is indicative of the deeper disorders may yet remain for future demonstration.

affect the parts devoted to sensation, increasing or diminishing sensibility, or causing disordered sensations which are erroneously referred to distant parts. These pains are not usually like head-ache, although affections of cords ultimately directed to the surfaces of the skull, &c for sensation, of course resemble disorders of these surfaces. No question exists as to the facts that affections of pericranium of the skull, and of dura mater, do cause true head-ache. The main question, perhaps, is what else may cause head-aches, as to brain disorders.

It does not appear determined that any affections within the arachnoid, and still less that any affection of the central parts of a hemisphere, produce headache.

If disease in the cerebellum at different times, or in different cases, be attended with pain in the occiput, pain in the frons, or no pain at all, we necessarily come to doubt all connexion between the existing disease and the pain. Countless capillary processes in sensitive and in other tissues have no proper trace.

For years I have expressed distrust of all the supposed seats of head-ache within the dura mater; I now propose an inquiry somewhat formally into the degree of probability attaching to this opinion. Perhaps in the main it may be made to appear that confined diseases in the brain are without pain; that pain supervenes much in proportion as these diseases extend to or approach the surface, and that circumstances of diffused capillary disorder which most certainly involve the sensitive membrane are most connected with pain.

As we have seen that experiment and disease afford very little evidence of sensibility in many of the viscera of the trunk until the external or reflected serous layer, or rather, until the sensitive tissues upon it, become acted on; so the same may apply yet more strictly with regard to brain substance as connected with head-ache.

Andral inquires (Spillan, 171) why are the cases of brain softening with head-ache completely identical with others in which no head-ache is present? This is at once the exposé of the error, and of the difficulty, and the ground for the true reply. Andral freely admits that with very similar

local disorganizations the pain may be referred to the point affected, to any other point, or to most parts of the skull variously, irregularly, and indifferently. It is, however, necessary steadily to remember that head-ache, whether in brain or bone, leaves no proper trace.

Half the cases of brain softening are unattended with mental disturbance, and as to headache the patient freely declares himself to be at ease. The most constant sign is some lesion of motion, or feeling in the extremities, so much so, that we might draw a line from pons to paries; set headache at one end, and next to this mental disturbance, and leave the remainder for the lesions of motion, and for those disordered functions of the limbs, which arise from affections of specific brain tracts.

Andral refers, with just satisfaction, diagnostically, to a remark of Rostan's, concerning the cases of hemiplegia, where the only free hand indicates pain in the side of the head opposite to that of the palsy, and we shall find commensurate advantage whenever we can connect defined and partial pain in the head with any other distinct sign of local brain lesion; but such pain may yet be only disordered dura mater.

Andral seems to acknowledge—but with a little reluctance—that the whole course of common apoplexy may be unattended with pain. Abundant corroborative cases, however, are to be found in all writers on this point.

It is sufficiently apparent, in most diseases of the brain, that the attendant headache does not follow a similar course to the disease. The pain either precedes by weeks, or it supervenes or declines at any period of the course, and I cannot explain my view better, than by describing in the head what we daily see in progress under the skin—diffused disorder, including dura mater, leads to a central suppuration, and the surrounding action, together with the parietal pain, may subside or fluctuate until increasing deposition of pus, pressing in the most yielding direction, or extending on all sides, again invades sensitive tissues. We need not wonder that brain should suppurate before the meninges even cohere, or before they have permanently distended capillaries.

There is a common case which serves well to explain many particulars of the

cases in question. Disease of the internal ear, and headache, vary indefinitely. With increased cachexy the aggravations proceed, and death discovers an abscess an inch deep in the adjacent cerebrum or cerebellum. The dura mater seems nearly sound, the serous membrane may appear unaffected, and the surface of the brain healthy, or nearly so. Perhaps it is more forward to decompose. I do not hesitate, however, to conclude, that contiguous sympathy of capillaries explains the origin of the abscess. The peculiarities of the vessels of the head—of the diathesis determining first the painful state of vessels, and then the suppuration in one part rather than other affections in parts adjacent, are still to be borne in mind here.

A man, æt. 66, was three years losing his sight: he had occipital pain two months; only slight vision of one eye; dull anxious wandering; speech slow; three fits; coma.

A cartilaginous tumor was found against the corpora quadrigemina, cerebellum, and left hemisphere, with softening around; over the left choroid plexus there was ziss. of amber-coloured gelatinous effusion. (LOND. MED. GAZ. Sept. 1838; Haye's Jour. Feb. 1839.)

I would offer this case as an example of the kind of proof that is to be considered. Setting out with the physiological views of the several parts of the head, the reader will hardly examine a single case of head affection, without remarking some forcible illustration of the positions I have laid down.

We may continually see the worst forms of headache without affections of mind, of sense, or of motion, and without any trace of brain disorganization. This last occurs in every variety without headache.

Mental disturbances are attended with headache very much in proportion as the vascular disturbance is great in the meninges.

No other organic diseases in the head are so constantly accompanied by pain as those of the dura mater. None are so rarely painful as those of the central parts of the brain. The wider the disorder of the brain, the more varied are the signs, and the more frequently is there headache, and *vice versâ*. With limited brain disorganizations we may find the corresponding sensitive pairs affected; but it is much more usual to

observe the pain to be devoid of all correspondence, as to site, degree, and extent, except, perhaps, when a surface of the brain, or of the cerebellum, is greatly affected.

I cannot but conclude, that the more the observer is guided by these views, the more he will see cause to locate common headache superficially, and that even when pain chances to attend the most limited derangement at the centre of the brain.

36, Bedford Square.

AN ACCOUNT
OF
PROFESSOR MULDER'S
RESEARCHES ON THE CHEMICAL
PHYSIOLOGY OF RED COLOURING
MATTER OF BLOOD.

By DR. GOLDING BIRD,
Assistant-Physician to Guy's Hospital.
(For the Medical Gazette.)

THE appearance of Professor Mulder's "*Versuch einer allgemeinen physiologischen Chemie*," now in the course of publication, constitutes an important æra in the history of chemical physiology; the elaborate and successful researches of one of the most laborious and accurate physiological chemists of the age, being for the first time placed before the scientific world in an available form. Mulder having previously published his researches piecemeal, and generally in his native language (Dutch), which is scarcely understood by men of science out of Holland. It is to be hoped, that a translation by some one, both from chemical and medical attainment competent to the task, will before long appear, for the benefit of the English physiologist.

There is this very remarkable contrast between the works of Professor Liebig and Mulder; that whilst the former writer is characterised by the ingenuity and abundance of his hypotheses, the latter is content with a patient enumeration of facts, and so far as I have studied his work, scarcely advances a theory without fortifying himself with an accumulation of experimental data, for which he is chiefly indebted to his own labours in the Utrecht laboratory. It is this circumstance, indeed, which renders his work of such peculiar value to the physiologist.

In a former communication, I gave an account of Professor Mulder's researches on the chemistry of protein; the physiological relations of that substance having been since detailed by my friend Mr. Paget. I now purpose to give an account of the Professor's views regarding the nature of the red colouring matter of blood, a subject which has admitted of more discussion than perhaps any other in connection with physiological chemistry. The experimental researches of Mulder lead him to results differing *toto cælo* from the hypothesis of Liebig regarding the nature and functions of hæmatosine or red colouring matter.

Mulder sets out by observing that the functions of the red colouring matter must undoubtedly be an important one, inasmuch as it exists in such a large number of animals otherwise so distinct in their structure and habits, although at the same time it must be admitted that this substance is not absolutely essential to animal life, as it is wanting altogether in some tribes of animals. Regarding its origin, it must be assumed as being capable of being actually generated, *de novo*, in the organism, as it does not exist in the vegetable kingdom; consequently it cannot, like protein, be traced to the elements of food in the case of the herbivora. It is hence fair to presume, that if generated by the vegetable feeder, the carnivora must possess a similar power.

The colouring matter is normally enclosed in a sac or cell composed of a thin membrane, consisting chiefly of protein, and capable of admitting of percolation through its walls under certain circumstances, although it generally retains the coloured fluid it encloses sufficiently firmly to prevent its admixture with the serum. Within the sac is a nucleus of similar chemical composition to the membrane, and the whole thus organised constitutes the *blood-disk, globule, or red particle*.

It has been generally assumed, that hæmatosine exists in two distinct states in venous and arterial blood; the former containing, according to the received hypotheses, most carbon or carbonic acid, and the latter most oxygen. These distinctions are founded solely on differences in colour, and are unsupported by a single analysis. It was supposed, that in the lungs the red particles of

venous blood exhaled carbonic acid, and absorbed oxygen in altering their tint to that of arterial blood. It is now well known that analogous changes of colour are produced by merely immersing a piece of black venous clot in a saline solution, the vivid vermilion tint being assumed without any change in the proportion of oxygen.

A considerable proportion of colouring matter may be removed from a clot of blood by digestion in alcohol containing either sulphuric acid or ammonia.

The colouring matter of blood freed from other matters invariably presents the same constitution, viz. :—

44 atoms Carbon	=	264
22 ——— Hydrogen	=	22
3 ——— Nitrogen	=	42
6 ——— Oxygen	=	48
1 ——— Iron	=	28
		404

If a current of chlorine be transmitted through a solution of colouring matter of blood, the iron leaves the other elements, forming a chloride of iron, and the atom of metal thus removed is replaced by six of chlorous acid*, and the following compound is formed

During this process, the red colour of the hæmatosine is destroyed, and the new compound appears as a white flocculent precipitate. It must not, however, be assumed that the mere removal of the iron by the chlorine destroyed the colour, for that metal may be removed without materially affecting the red hue of the hæmatosine. For this purpose, let some dried coagulum of blood, (consisting chiefly of red particles, and protein compounds) be macerated in concentrated sulphuric acid; after some days, water may be added, and the remaining excess well washed on a filter. During the action of the acid on the clot, *hydrogen gas is evolved*, and the iron dissolves, forming a proto-sulphate, which passes through the filter. The coloured matter is left behind, preserving its original red hue,

* Mulder regards this acid (Chlorige-saure) as composed of CO_3 and not of CO_4 , as generally assumed. The former is the composition assigned to it by Count Stadion.

notwithstanding the removal of the iron, mixed with a combination of proto-tein, with sulphuric acid, in the following proportions :—

	C	H	N	O	
1 atom of iron-free hæmatosin	= 44	+ 22	+ 3	+ 6	
1 atom of protein	= 40	+ 31	+ 5	+ 12	+ 1 atom Sulphuric acid.
4 atoms of water		4		4	
<hr/>					
	84 + 57 + 8 + 22 + 1 atom SO ₃				

If, instead of digesting mere coagulum in the acid, pure red particles be substituted, the experiment is more satisfactory. For this purpose, allow blood as it escapes from a vein to fall into a solution of nitrate of potass. The coagulation of the fibrin is thus prevented, and a dense deposit of red particles falls to the bottom of the vessel; these, when well drained from adhering serum, and dried, may be mixed with strong sulphuric acid; *hydrogen gas is evolved just as when metallic iron is digested in the acid*, and after some days a solution of sulphate of iron is obtained, and the insoluble red colouring matter is thus left free from iron, but retaining its peculiar tint. The non-ferruginous hæmatosin consists of:

Having thus proved that the colour of red particles does not depend upon iron, Mulder next proceeds to combat the doctrine that these bodies are "carriers of oxygen," and that iron is oxidised during respiration, as assumed by Liebig: an assumption which forms the basis of that philosopher's theory of respiration.

It appears that iron is so intimately connected with the other elements of

hæmatosine, that it cannot be removed even by long digestion of red particles of blood in hydrochloric or dilute sulphuric acid. Consequently, even if no other explanation of the absorption of oxygen during respiration existed, these facts are sufficient to show the high impossibility of the iron being oxidised in the lungs, since it will not yield to hydrochloric acid. The converse has indeed been stated by Liebig, but his statement that weak acids remove iron from clots of blood, is explained by the fact that all the albuminous elements of blood contain a portion of this metal in a state which admits of ready solubility in acids.

If, as is assumed in Liebig's theory, sesqui-oxide of iron existed in arterial, and proto-carbonate of iron in venous blood, almost any dilute acid would be capable of dissolving out the oxide, which, as we have seen, is not the case. The fact of the iron really existing in the metallic state is moreover strongly supported by the evolution of hydrogen gas which occurs when sulphuric acid is digested on the clot, as pure red particles; this metal probably exists as an integrant component of hæmatosine, just as iodine does in sponge, sulphur in cystine, and arsenic in the curious kacodyl series of compounds; thus:—

Further, if iron existed as sesqui-oxide strong sulphuric acid, the residual iron-free matter ought to consist of—

$C_{44}, H_{22}, N_3, O_{4\frac{1}{2}}$, instead of C_{44}, H_{22}, N_3, O_6 , which is really left, for hæmatosine, = $C_{44}, H_{22}, N_3, O_6, Fe - Fe O_{1\frac{1}{2}} = C_{44}, H_{22}, N_3, O_{4\frac{1}{2}}$

—consequently the actual results of analysis are opposed to Liebig's theory.

From experiments of Scherer, it appears that when scarlet arterial ox-blood is beaten to separate fibrin, and diluted with thrice its volume of water, it assumes a venous hue, and a current of oxygen gas transmitted through it does not redden it. The mixture of a little oil, milk, chalk, or gypsum, with the black blood, instantly restored its

florid hue, so that the red colour is owing to other circumstances than the absorption of oxygen. Scherer indeed concluded that the arterial colour depended on white opaque particles diffused through the fluid.

It appears to have been observed by Hewson, that bright red blood-corpuscles are always bi-concave; these may therefore be supposed to reflect a great amount of light, and thus act like the

white reflecting particles of chalk, milk, &c., in Scherer's experiments. In dark-red blood, the corpuscles are convex, and the enveloping membrane much thinner than in bright-red blood, so that light passes easier through them, and they readily burst, allowing their contents to mix with serum when blood is largely diluted with water: the well-known effects of saline solutions in reddening blood is readily explained by their producing exosmosis, and consequently, a partial emptying of the sac of the blood-corpuscles, which then becoming doubly concave mirrors, reflect much light, and cause the fluid containing them to present an arterial tint. A current of carbonic acid gas will cause such blood to become again black, by altering the form of the reflecting corpuscles, causing them to become bi-convex.

Protein readily combines, as we have seen, with oxygen, and forms a soluble tritoxide and insoluble binoxide, both frequently being formed simultaneously in health, and abundantly so in inflammation, constituting the buffy coat of inflamed blood. In the process of healthy respiration these oxides are formed, and immediately tend to solidify, as we see in "buffy coat;" they fix round each blood-corpuscle, therefore; virtually making their investing membrane thicker and more opaque, better enabling it to reflect light, and producing the bright red colour of arterial blood. If we conceive such a layer of oxy-protein (buffy coat) to form round each blood-disc, and to go on contracting, it would produce a "cupped" state of two surfaces of the corpuscle (just as is seen on the upper surface of inflamed blood), and by converting them thus into double concave lenses, produce a condition more favourable for the powerful reflection of light, and necessarily heighten the light red colour of arterial blood. On reaching the capillaries, the coating of oxyprotein is removed, the protein being employed for the repair of tissue, and the oxygen used for effecting the metamorphosis of effete and exhausted structures. The corpuscles losing their opaque covering, have their power of reflecting light diminished, their concave surfaces are lost, and the whole assumes a venous tint.

When a piece of black venous clot

is exposed to the air, it becomes red, in consequence of absorption of oxygen, not by the colouring matter, but by the protein; and the opaque oxy-protein causes the mass to reflect a red light, just in the same manner that dark venous blood does when in a vessel of "milk-glass." A drop of an alkaline fluid destroys the red colour of the clot by dissolving the oxy-protein.

Digested in salt and water, a black clot becomes red by partly emptying the corpuscles by exosmosis, and by thickening their investing membrane. The subsequent washing with water removes the salt, fills the corpuscles by endosmosis, thus altering their figure, and diminishing their reflecting power, and causing the clot to look nearly black.

All dilute acids, even the carbonic, blacken blood by altering the figure of the corpuscles, and dissolving the reflecting layer of oxy-protein round them.

Scherer regards the conversion of black venous into red arterial blood to depend upon the loss of carbonic acid, the absorption of oxygen, and the presence of reflecting particles of the white opaque contents of the thoracic duct. Mulder believes the simple formation of the oxides of protein to be a sufficient explanation. He does not consider that when carbonic acid blackens blood it affects the red particles further than by physically altering their investing membrane by diminishing its reflecting power. He refers the very black colour of portal blood to such a state of the corpuscles, either from the action of carbonic acid, or more probably of a little free alkali (soda).

The real function of red corpuscles remains yet to be discovered; all evidence appears opposed to their playing any part of importance in the process of respiration. Mulder believes that they are generated from the normal constituents of the blood in the general circulation. Their destination is obscure: if they undergo a metamorphic change prior to their development into living tissue, the products of their decomposition may be probably traced to the *bilifuscin* of the bile. (In all probability, the red particles act physiologically, as has been suggested, in constituting the elements of many living tissues, playing the part of

nucleated cells, as, indeed, is now pretty generally admitted.)

The following is a brief summary of the above views of Mulder:—

1. The red particles of blood contain iron as a simple element, combined with nitrogen, carbon, hydrogen, and oxygen, and are chemically identical in venous and arterial blood.

2. In traversing the capillary system of the lungs, the protein of the blood combines with oxygen, generating a compound analogous to "buffy coat," which forms a contractile covering to the blood corpuscles; causing them to become more opaque, and giving them the figure of doubly concave lenses.

3. In the general capillary circulation, the oxy-protein surrounding the corpuscles is decomposed, the oxygen being used for dissolving old tissue, and the protein deposited to supply its place. The corpuscles lose their reflecting concave figure, and become more transparent by this change.

4. The difference of colour between venous and arterial blood depends solely upon a physical difference in the surfaces of the corpuscles; being semi-opaque concave mirrors in the latter, and mere transparent convex bodies in the former.

5. Whatever alters the figure of the corpuscles, or gives blood the power of more powerfully reflecting light, at once alters its tint.

6. During respiration, the colouring matter of the blood undergoes no change, and indeed plays no part, either as a whole, or in regard to the iron which exists as an element in it.

7. Iron is not essential to the red colour of blood corpuscles, although its presence is probably necessary for their formation and development.

made within the last few years than in our knowledge of urinary diseases, and of the connection between the actions of the kidneys and the functions of the digestive organs and skin; and the information derivable from an examination of the urine under different states of disease is so important as a guide to therapeutic treatment, that no one can be considered competent to practise his profession who neglects to avail himself of the indications which this excretion affords. It is impossible for any one to estimate more highly than ourselves the researches of our countryman, Dr. Prout, in this department of medical science; and the fact that his work on *Stomach and Urinary Diseases* has reached a fourth edition is a sufficient proof of the value and utility of his labours. There are, however, few medical works more difficult of "digestion" than Dr. Prout's *Treatise*; and we believe that its study will be greatly facilitated by the excellent shorter and more rudimentary work by Dr. Bird, which we now introduce to our readers. We can fully bear out the words of the author of the work which heads this notice, when he states that "in mixing with medical men in practice, I have often found them in want of some work which would enable them readily to discover the nature of a deposit in the urine, and succinctly point out its pathological and therapeutical indications. To be available, it was necessary that such a work should not exceed the size of a small manual, and its contents be so arranged as to admit of ready reference, and thus be more fitted to act in the humble office of pioneer to more elaborate, and more diffused sources of information."

Our readers will recollect that in the early part of last year a short course of lectures on the diagnosis and pathology of urinary sediments by Dr. G. Bird was reported in this journal. These lectures were afterwards translated into German, and collated into a volume, which was published at Vienna. The perusal of this induced the author much to extend, indeed nearly to rewrite, the whole subject, and he has now ventured to place this work before his professional brethren as the result of many years' close observation in the field of public experience which he has fortunately had at his command.

ANALYSES AND NOTICES OF BOOKS.

"L'auteur se tue à allonger ce que le lecteur se tue à abrégé."—D'ALEMBERT.

Urinary Deposits, their Diagnosis, Pathology, and Therapeutical Indications. By GOLDING BIRD, A.M. M.D. Assistant Physician to, and Lecturer on Materia Medica at, Guy's Hospital, &c. Churchill: 1844.

THERE is no department of pathology in which greater progress has been

This task Dr. Bird has ably performed, and he has produced a work which will be found of great utility to students, and to medical practitioners desirous of becoming practically acquainted with urinary pathology at a small expense of time and study. The directions given for the detection of urinary sediments are clear and accurate, and easily followed by persons but imperfectly acquainted with chemistry. The author has also pointed out the facility afforded by the microscope in the examination of these deposits, and has given some accurate representations of them, by the aid of which the observer may in a few minutes learn the nature of any variety of sediment. His observations on the pathology of urinary deposits evince much talent and study of this difficult subject, and the remarks on their treatment, though brief, are judicious and practical.

Perhaps the most interesting chapter in this volume, because containing the most novelty, is the one on the chemical pathology of oxalate of lime (oxaluria). Crystals (octohedral) of this deposit have, until recently, been regarded as of very rare occurrence, and we are chiefly indebted to the researches of Dr. Bird for showing the error of this opinion, and that this salt, when present, is easily overlooked. He is inclined to believe that the formation of oxalate of lime is connected with the depressing influences always more or less active in large and densely populated cities; and he declares, as the result of his experience, that in the cases of disease occurring in this metropolis, *the oxalate is of far more frequent occurrence in urine than the deposits of earthy phosphates*. We regret that we have not space for the directions which are given for the detection of this deposit, but must refer our readers to the work itself. Our author speaks highly of the influence of colchicum in causing the disappearance of this salt; and it may be interesting to state that Dr. Bence Jones* has shown that it is frequently present in cases of rheumatism; confirming the fact of the close connection between the uric acid deposit and octohedral crystals.

* See the new volume of the Medico-Chirurgical Transactions.

MEDICAL GAZETTE.

Friday, December 27, 1844.

"Licet omnibus, licet etiam mihi, dignitatem Artis Medicæ tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

THE DUTIES OF THE STATE IN REFERENCE TO THE PRAC- TITIONER OF MEDICINE.

THE more we think on the plan of dealing with the medical profession which was thrown out in broad outline in our last week's number, the more we are disposed to regard it as the best and most feasible for all parties;—for the public first; for the medical profession next, and for the minister who proposes to legislate for that profession in fine. Did we want farther confirmation of the justice of this conclusion, we should find it in several excellent letters that have been addressed to us on the subject, and from the remarks which we have heard incidentally made upon the general scheme by more than one of the best heads in the profession.

The progress of things in all policed countries does in fact appear to be from private enterprise or speculation to more public means of carrying out specific ends: An individual trader opens up some vein of commerce; it is obviously rich; he tries it for a time by himself, but soon discovers it too extensive to be worked to the best advantage by the limited power of his own capital and resources; he associates another with him, and to the original firm is added an "and Co.;" the matter is still found beyond the strength of the original projector, and his friend Co., upon which a larger trading company is formed, managed by a Board, and having numerous shareholders among the capitalists of the kingdom. This Company prospers; it not only carries on a vast and lucrative commerce, but it acquires settle-

ments in the countries beyond seas with which it trafficks; these settlements extend; the occupants upon sufferance at first of a few square feet of land for the purpose of storing their merchandise, find themselves in the end independent sovereigns of a vast continent, with a standing army of 150,000 men under their command, and more than a 100,000,000 of subjects doing them homage. The government of the native country of these bold merchants confirms them in their enterprises for a long succession of years; it grants them one charter of incorporation and exclusive privilege after another, and at length enables them to outgrow the need of all protection; each exclusive privilege, each monopoly, is, in fact, discovered by and by, to be prejudicial to the general interests, and after due notice given, the State resumes its most essential grants, throws open the trade to its subjects at large, and itself assumes the virtual sovereignty in the territories won by these merchant princes.

It is not, and cannot be otherwise with associations for the promotion of matters of science, or of art, especially when these touch, as medicine does in each and all of its departments, upon police. Royal Societies, and Royal Academies, indeed, are private associations, with the state seal of approbation upon them; and so they may remain; the state is not required to interfere peculiarly in their management and proceedings; the matters they occupy themselves withal do not bear upon the common weal. It is otherwise with medicine; every day shows more and more clearly that the enlightened physician is to become the future guide of the statesman in the vast efforts he has yet to make to improve the physical condition of those over whom Providence has set him in authority, and so to raise them in the scale of moral excellence.

The wants of society, for instance, lead the general dealer, the *grocer* of the country, to add a stock of drugs or medicinal substances to his other wares,—to his spices and liquors, his oils and honeys, pickles and condiments, and confections. The traffic in drugs extends; the department has particular attractions for a certain order of minds, and as knowledge enlarges, the owners of these minds cast off the grocery business; from simple dealers in medicines they inform themselves of their virtues, and of the circumstances in which they are said to prove useful; they are soon consulted on diseases at home, and then they begin to go abroad in the more serious cases—the grocer has, in fact, merged in the physician, and the apothecary of the last century: the prototype of the general practitioner of the present day is the result.

Other men, of more liberal education and fortune, scholars, often priests, who had never engaged in trade, but who have nevertheless an innate taste for the natural science of medicine, give themselves up to this art and mystery; and thus is the medical man of learning, the prototype of the present physician, produced—the apothecary in everything, save that he does not deal in the medicines whose virtues he studies and prescribes.

But neither the apothecary nor the physician wholly meet the wants of society in reference to medical attendance. There are certain operations of surgery;—blood-letting, tooth-extracting, and, in cases of accident or emergency, even amputation, that must be undertaken. Neither the apothecary nor the physician hold these within their province, and another functionary must be found. From his practice with edge-tools upon the excrementitious portions of the body, the beard and the hair, the barber appears at an early age to have been

thought the fittest person in the commonwealth to venture beyond the surface; from drawing blood accidentally, it was probably deemed logical to conclude that he was also the proper man to draw it on purpose; and so the barber-surgeon, the original of the present member of the Royal College of Surgeons, rose into being.

But the measure was not yet full: to say nothing of the increase in the number of articles of the *materia medica* brought about by the lapse of time and the extension of natural history, chemistry has arisen to create hundreds of new and most energetic compounds that powerfully influence the body in a state of health and disease. These articles, these compounds, were found subject enough to engage one man's attention, and it was seen that the preparer and compounder of medicines might be advantageously separated from the practitioner of physic. Hence has been produced the modern chemist and druggist—the indispensable adjunct of the physician and surgeon, of the true professional man, in the exercise of his calling.

Like draws to like; men with a community of purpose and of interest, pursuing the same path in life, soon herd together, first in smaller and then in larger numbers; and the apothecary, the physician, the surgeon, and the chemist, having each been seen useful members of the state, find favour in the eyes of successive sovereigns, who associate them into Companies or Colleges, and from time to time grant them charters, conferring peculiar privileges and immunities, rather, however, with a view to their protection severally against interlopers, than with an eye to the public health and safety. These associations by and by begin testing by examination or otherwise the worthiness of those who seek admission into their body; they next make certain requirements as to education,

preliminary and professional, before they will consent to receive candidates for acceptance; and they at the same time begin to grant diplomas or certificates, as assurances to the public of competency in a certain determinate walk on the part of the holder. These private associations finally acquire such a standing in the general esteem, that Government sees fit to require of aspirants to medical offices in the public service, that they should have successfully undergone the examination, and obtained the diploma, of one or other of them, before it will hold them eligible for an appointment. Government, however, has never forgone its title to be satisfied of the actual worthiness of the possessors of these diplomas by boards of its own choosing, and has by this means—by its Army and Navy Medical Boards—acted as a most salutary check upon the licensing bodies. Hitherto, nevertheless, Government has obviously worked by means of associations or corporations to a greater or less degree private,—apart from, and not dependent on itself, at all events. Our own opinion is, that this state of things should cease; that precisely as in the case of the East Indies, and our other colonial possessions, the time has come when the interests of all parties make it imperative on the Government of this country to take the business of licensing the medical practitioner generally, for the community as well as for the army and navy, into its own hands.

The several institutions connected with medicine, have done good service so far; the discontent that has been waxing in the medical profession for years, and the open discord that has but just broken out between the chartered institutions and the great body of the profession, must satisfy all unprejudiced persons that, in their present shape, these Institutions have outlived their destinies; that they are no longer fitted to meet the wants of the times, that in

some instances they are even challenged with having interests opposed to the general good, and that they ought now to be exonerated from the business of examining into the competency of individuals to undertake the responsible duties of medical practitioners.

When we look dispassionately at the storm of discord and difference in which we are at this moment involved, we see it entirely owing to the clashing of one interest, or of one presumed interest, in the profession—of one Royal College or corporation, of one class or grade of the profession against another; the Royal College of Surgeons of Dublin against the Royal College of Surgeons in London and its members, especially those among them who are settled in Ireland, and whom the Irish College is directly interested in reducing to an inferior grade*; the Royal Colleges of Surgeons generally, and the Universities, that of Edinburgh in especial, against the Apothecaries' Company; finally, and most disastrous of all in its immediate and social effects, of one grade or department of the profession against another—physician and pure or operating surgeon against general practitioner, general practitioner against physician and hospital surgeon.

All this should end, and it can only end satisfactorily in one way; by reducing the chartered colleges and corporations to a footing of equality in reference to the grand bone of contention among them, the power of conferring licenses to practise medicine in any of its branches as a means of making money. These institutions, if reduced to their pristine state of pri-

vacy, have the elements of great good inherent in them; they may again become, what they have long ceased to be, means for the advancement of the art and science of medicine. And in returning to the "post of honour," which for scientific bodies never can be other than "the private station," they will in fact lose nothing: the Royal College of Physicians have long ceased to exercise their right of insisting on every gentleman who settles in "London or within seven miles of the same," joining them; yet no one thinks it less incumbent on him now than formerly, to present himself for reception in Pall-Mall when he brings his Doctor's diploma into play in London. The Royal College of Surgeons never had any right to require members to join them; yet have they for years been deriving an income of ten or twelve thousand per annum. from the voluntary afflux of parties who held it their interest to obtain their diploma. In the same way with reference to the Universities, alike of England, Scotland, and Ireland: there has yet been nothing necessary or compulsory about the degrees they have granted; these have always been optional, yet not the less eagerly have they been sought after, and prized on that account. As to Apothecaries' Company, this is the only institution that would be unequally dealt with in our scheme of relieving all the institutions connected with the profession of medicine from the burthen of licensing the practitioner; but it seems by common consent agreed that the association of a liberal profession with an offshoot of the old Grocers' Company, was a most unlucky conjunction, and that as it ought never to have taken place, so ought it now to come to an end. The members of this company themselves give up the point; they are ready to ally themselves with the general practitioners who are now struggling for a

* We have already explained this matter. This Irish Royal College held themselves literally robbed of a large sum every year for some quarter of a century or so by the English Royal College; the Irish charter of incorporation being so framed as to prevent the young men educated in Dublin from obtaining their diplomas there, but forcing them to London for their certificates.

charter of incorporation, and to quit their old name and designation.

Our scheme of medical reform, then may be briefly set down under the following heads:—

1. A Supreme Council of Health and Education, chosen by the Home Minister.

2. Boards of Examiners chosen by the Council, one for each division of the kingdom, and holding its sittings in London, Dublin, and Edinburgh, respectively, to pass which, should be imperative on every one who aspired to the responsible duty of practising medicine in any of its branches or departments.

3. Existing Institutions, and Institutions which the circumstances of the times have made necessary.

a. The UNIVERSITIES, which should have the privilege, as heretofore, of conferring honorary titles or degrees, but which should not have any power of granting a license to practise medicine in any of its branches, independently of the Government board.

b. The ROYAL COLLEGES OF PHYSICIANS, which should be private associations for the furtherance of the science and art of medicine.

c. The ROYAL COLLEGES OF SURGEONS, which should be private associations for the promotion of the science and art of surgery.

d. A ROYAL COLLEGE OF GENERAL PRACTITIONERS. — An Institution with this title, is only made necessary by circumstances. It might by and by become a *Royal College of Obstetricians*. At present, however, it appears altogether indispensable. The general practitioner of the present day, is a man of too much importance to be left uncared for. He is, as an excellent writer* has well said, "The ordinary attendant of the great bulk of the population, and

now only summons the physician to his aid in cases of difficulty and danger. The expectant mother in pregnancy is under his direction; he conducts her through the often critical period of parturition, and her off-spring from the moment of birth is his accustomed charge. Can a medical man have more important or more responsible duties confided to him? And is it not the duty of the legislature to take care that no man shall be licensed to undertake these duties without having adduced proofs of being qualified to perform them? These are questions which admit of being answered in one way only. *Upon the skill and judgment of the General Practitioner depend mainly the health of the community.*"

e. A ROYAL COLLEGE OF CHEMISTS AND PHARMACISTS,—an institution that has become quite imperative, and without which no scheme of Medical Reform can be held even tolerably complete, though it appears very generally to have been entirely overlooked.

Whether these institutions ought to be represented in their corporate capacity in the Council of Health and Education, or not, we are still undetermined. We see certain objections to their being so represented, and also certain objections to their being left out of the reckoning. Probably, on the whole, they would be better left unrepresented; the medical men who had seats in the Council of Health and Education would almost, as matter of course, be associates of one or other of these institutions, so that they would still be represented indirectly. Were one represented, we would have all upon the same footing.

But we would not enter into particular details now; we shall probably find an opportunity of doing so at another time.

* * Sir James Clark, "Second Letter on Medical Reform," pp. 8 and 9.

ST. MARYLEBONE PARISH INFIRMARY.

A CORRESPONDENT writes as follows: "The Board of Guardians have determined on not filling up the vacant honorary surgeoncy to this institution. A very active canvass had been going on, however, in favour of several candidates for the appointment; but, from what you say some fortnight back of the offer of advice gratis by the young aspirant for employment at Hastings, I believe you will be pleased to learn that the offers of gratuitous services to the wealthy parish of St. Marylebone have been definitively declined. And surely, sir, when it is considered that the parish paupers are entitled by law, by right, and not as a matter of mere voluntary charity, to good and proper medical attendance; and that the parish which is bound to provide this aid is, in this instance, notoriously very rich; it can neither be just nor benevolent to expect of our poor profession to *give* services which, on every principle of justice, ought to be *paid* for, as well as those of the clergyman or lawyer under similar circumstances. More than this, I think you will agree with me in viewing the decision of the Guardians as a wise one. It is certain, in a general way, that the best services are to be had for payment: in short, that the best interests of the poor, of their legal guardians, and of our own profession, have been had in view when the Guardians came to the determination just mentioned.

THE GRAND OBSTACLE TO THE SUPPRESSION OF QUACKERY.

WE have another opportunity this week of referring to a Provincial newspaper—a conservative journal, we apprehend—and extracting the following list, to put those among our readers who are sanguine enough to hope that they may outlive authorized quackery out of their vain imagining:—1st. "Mr. Thomas's Succedaneum for filling decayed teeth," and "Method of fixing artificial teeth," which last we are informed "has obtained the approbation and recommendation" of Sir James Clark, Bart., Dr. Locock, Dr. Ferguson, Dr. Bright, Sir B. Brodie, Bart." &c. &c. We have been desired by one at least of the distinguished men thus im-

pudently paraded, to say that there is not one word of truth in the statement; that he has never either approved or recommended Mr. Thomas's method of fixing artificial teeth, and that his name is used without all authority. 2nd. A new and important edition of the "Silent Friend in Human Frailty;" followed by the "Cordial Balm of Syriacum" and the "Purifying Specific Pills." 3rd. "Dr. Grandison's Charity Pills." 4th. "New wonders every day!—a cure for all! Holloway's Ointment and Pills." 5th. "Worsdell's Pills, by John Kaye." 6th. "Rowland's preparations for the hair, the skin, and the teeth." 7th. "Parr's Life Pills." 8th. "Wilkinson and Co. Consulting Surgeons, their Purifying Drops and Secret Medical Adviser." 9th. "Unparalleled Success! Wray's Balsamic Pills." 10th. The 21st Thousand, "Manhood," &c.

This last is not very long; nevertheless it fills, along with two PUFFS, one dedicated to Holloway's Salve, t'other to Thomas's Teeth, upwards of four columns of the newspaper whence it is extracted, and as the payment is according to the length, the value of the advertising practitioners and vendors of specific medicines to the proprietors, may be imagined.

ROYAL COLLEGE OF SURGEONS, OF EDINBURGH.

WE have a letter from the Secretary of the Royal College of Surgeons of Edinburgh, authorising us to contradict the rumour that any proposition had been made for the sale of the museum of that old and excellent institution. It had only been "the greater pity" had any such proposition been absolutely made. Some wicked members of a rival diploma shop probably spread the report. We trust, with new arrangements, that the Royal College of Surgeons of Edinburgh will soon find itself in a condition to extend its museum.

THE SANATORIUM.

WE have a letter from Dr. Hitchman, the resident medical officer of the Sanatorium, informing us that mesmerism is neither believed in, nor practised, by any of the medical gentlemen officially attached to that useful Institution. He seems to think that our notice of the

case of removal of the mammalately performed there, might lead to a contrary presumption. We do not see the matter in this light; but, lest any mistake should occur, we hasten to mention Dr. Hitchman's disclaimer.

MISS MARTINEAU AND MESMERISM.

To the Editor of the Medical Gazette.

SIR,

ALTHOUGH it may be proper that judgment should be suspended regarding the case of Miss Martineau, it is by no means necessary that her letters on mesmerism should be allowed to pass without comment, more especially as she and her mesmerist have nightly parties for the purpose of witnessing their performances, and spare no pains to make proselytes; and such as remain sceptics, or attempt to investigate the subject, are assailed in no very measured terms, as is evidenced by the allusion to Dr. Forbes's exposure of Alexis, and also her very uncourteous, not to say coarse attack, upon the gentleman whom she accuses of singing J.'s arm, and calling fire! It was on this same occasion that it is stated that J. saw the vision of a shipwreck, her cousin being on board the vessel that was lost; but though Miss Martineau pleads ignorance of the fact, the account of the wreck was well known in the village long before the hour at which this girl was mesmerised, and it is equally well known that she had been out in the village, and could not fail to hear the news: it would be satisfactory to learn also whether Miss Martineau herself was not already acquainted with all the particulars.

It is not my intention to go through Miss Martineau's letters, but principally to mention one fact, which will at once stamp the value that should be set upon these communications; Miss M. herself appears to be imposed upon, and is unconsciously lending herself to impose upon others; her judgment is perverted, her mental faculties obscured, and she views everything through a false medium; her mesmerist has worked upon her naturally excitable imagination, and induced her to receive as truths, things and statements, which a more cool observer would at once detect as fallacies; for example, that the somnambule cannot hear a conversation that is carried on in her presence, unless the speaker is brought into mesmeric communication with her. When this fact is known, it will no longer appear extraordinary, that the answers of the somnambule should be in exact accordance with the wishes and expectations of the mesmerist; and if their neophyte was as pure and

unsophisticated as Miss M. believes at the commencement, she could not by possibility be placed in circumstances better calculated to teach her dissimulation and hypocrisy; and it is not extraordinary that Miss Martineau should believe that the mind of the somnambule should mirror that of the mesmerist, when the questions to be proposed, and the answers expected, are openly canvassed in the presence of the somnambule.

What I have now said will be sufficient to shew the fallacy of Miss M.'s conclusions, based as they are upon so worthless a foundation.

There is much, very much, in Miss Martineau's letters, which is wholly unintelligible a mere farrago of words, conveying no meaning, and which to weak minds may serve to invest the subject in mystery, but which in reality only betrays the emptiness of the source from whence it sprung.

There is much more in these letters to find serious fault with; they are calculated to undermine the principles of the christian faith, and it has become high time that all well-thinking and well-principled people should set their faces against a pretended science, which is capable of being thus perverted.

I should not probably have troubled you and the medical profession with this letter, had it not been for the continued attempts which are made to unite mesmerism with the science of medicine; it becomes therefore the duty of every one interested in preserving the healing art from so debasing an alliance, to make known whatever comes to their knowledge, which exposes the fraud and deceit of the mesmerists.

I remain, sir,

Your obedient servant,

VERITAS.

To the Editor of the Medical Gazette.

SIR,

I APPROVE highly of your excluding from the Gazette, mesmeric wonders and controversies: "Pencilings," and articles on animal magnetism, greatly disfigure the pages of a contemporary journal.

Your correspondent, Mr. Chatto, must be credulous indeed, if he supposes the public, or the votaries of mesmerism, would be satisfied that an inquiry had been "patient, deliberate, and candid," were a committee of hospital surgeons to pronounce that *science* (?) as a means of preventing pain during operations, a *useless pawing and mummery*.

Mr. Chatto must not conclude that because hospital surgeons are not always before the public endeavouring to refute the wild and visionary statements of mesmerists, homœopathsists, and hydropathsists, that they have nevertheless failed to test the truth and

correctness of what these professors assert ; such a trial has long since been forced upon many of them by the reckless daring which has characterised the numerous statements which have from time to time been published. Instances of surprising insensibility to pain, or *power of concealing it*, are common enough ; only on Sunday evening last, I had to amputate the fore-arm, (an operation much simplified, as are other amputations, by the flap incisions, as recommended by Mr. Liston) for a gun-shot injury, which had destroyed the hand and wrist, perished one eye, and closed the other. I bethought me at the time how hypnotism, or mesmerism, would have been applicable to the case ; however, no such *aid* (?) was needed ; the man bore the operations without even a moan at "the crunching of the bone." I could name three other instances out of seven capital operations which I have been called upon to perform in hospital and private practice during the last seven or eight weeks, where the operations were endured with the greatest fortitude, and without a murmur ; and in traumatic amputations, I have frequently observed the same tolerance, or freedom from pain. The fact is notorious—mesmeric exhibitions are only suited, as Dr. Dickson says, to "dyspeptic men, and hysteric women," nervous personages, whom a straw or feather may move, and who swoon, or what not, at even the thought of blood being shed ; and of this Mr. Chatto can be satisfied by attending the operations at the metropolitan hospitals, if he be not in the habit of operating himself. Sir B. Brodie's "Nervous Affections." Mr. Travers' "Inquiry on Constitutional Irritation," and Dr. Gavin's work on "Feigned and Factitious Diseases," abound in nervous and other freaks of every description. A brief account of the cases of M. Cloquet, Mr. Alcock, Dr. Oliver, and of Sir B. Brodie, may be read in the Medical Gazette, of Dec. 1842, and other journals.

Hospital physicians and surgeons generally, do not, I believe, call into question "the effects of mental attention upon bodily organs," or deny that there may be instances of "surprising insensibility to external impressions, while the imagination may be in activity ;" but they refuse, and I think properly, to notice the mesmero-phrenomagnetic absurdities which too frequently are paraded before the public for no other object than notoriety and private gain. I should expect as much benefit to arise from a committee of inquiry, composed of hospital surgeons, as suggested by Mr. Chatto, as some time since resulted from one formed in this town, of members of the law, physic, and divinity, with a sprinkling of "young Lynn," for the purpose of examining into the merits of mesmerism and phrenology,

and which was presided over by a patient of the Rev. Dr. Moseley.

You are at liberty to insert or reject this hasty letter ; I am prepared for the thunderings of the maudlin sentimentalists. The public ought not to be deluded by the wholesale charges of prejudice, indifference, and inhumanity, too frequently alleged against the medical profession of the present day.

I remain, sir,

Your obedient servant,

CHARLES COTTON.

Lynn, Dec. 18, 1844.

ON THE APPLICATION OF MESMERISM TO SURGICAL OPERATIONS.

To the Editor of the Medical Gazette.

SIR,

IN your number for Dec. 13th is a letter, signed "John Chatto," suggesting that "a committee of hospital surgeons be appointed for the important investigation of the claims of mesmerism to the power of rendering persons insensible to pain during the performance of surgical operations," and accusing the hospital surgeons of "unyielding scepticism," because "he has not heard that even one has employed the facilities which the charity with which he is connected may afford "for this purpose ;" even the medical corporations are impugned because "the hospital surgeons have, to use the mildest terms, shown a culpable apathy, and a want of a due recognition of the responsibility of their position in the profession."

It may be, sir, that the surgeons in question have a trifling regard to their own characters, and the reputation of their hospitals, and that the governors of these institutions may be actuated by the same spirit as those of the North London Hospital, and quietly recommend the resignation of any officer who delegated their functions to the votaries of this new-old theory. As, however, what is good for the cat may be good for the kitten, I beg to suggest that Mr. Chatto should shame these negligent people into action by forming a committee of six medical friends, with himself as their director or secretary, to perform the following experiments :—

1st. The committee may be formed by selecting such friends as may happen, for the convenience of the experiment, to possess a tooth of which they desire to be rid : let an accurate note be taken of the degree of sensibility in each individual before the operation, and let Mr. Nasmyth be requested (and his love of science would doubtless lead him to consent) to be present at the extraction of the offending molars by any

operator whom the committee may select, in order that he may mark accurately the degree of contraction of the muscles of the face, or the elevation of the voice, or the pressure of the hands on the chair, indicating the pain felt by each member in succession; this degree being represented in numbers, which may be compared with the intensity of the mesmeric influence in each before the operation; and to prevent any chance of deception, the mesmeriser should make memoranda as to this or any other point of importance in the experiment before the trial begins, and deposit his notes, sealed up, in the hands of the secretary.

2d. Let each member of the committee be armed with an acupuncture needle, exactly one inch long and of moderate thickness, and let each in succession pass the needle into any specified part of the body of the other five members, the part to be punctured being selected by lot out of a certain number previously agreed upon in committee, so that no one may know where exactly to expect the puncture. To avoid danger to the members of the committee, no important organ is to be selected, and as there may be some confusion between material and moral sensibility, the committee may exclude the part marked out by the course of the gluteus maximus muscle. This experiment may be varied thus: first, each member may be mesmerised separately in a complete manner, and the other five may introduce their needles, one after the other, at intervals varying from thirty to ninety seconds between the successive trials; and secondly, all five may simultaneously employ their implements in different parts of the same person. In this way intensity of pain and duration of pain may be each represented, and a pleasing variety of experiments will be introduced, by which every source of deception or error is avoided, and the most sceptical hospital surgeon will not fail to be convinced. I say nothing, sir, of the satisfaction and conviction of the public, because the public is convinced very often at uncertain periods; only it unfortunately happens that they forget again what they have so often been informed of on the most indubitable testimony, from Mesmer himself down to Miss Martineau.

For my own part, sir, if Mr. Chatto and his six friends in committee will vouch for the success of these experiments, due details of the experiments being given, I have no doubt I can form a committee of hospital surgeons to try the efficacy of mesmerism on the *cat*, that is to say, in the greater operations of amputation or excision of the heart.—I am, sir,

Your most obedient servant,

ONE OF THE HOSPITAL SURGEONS.

Dec. 27th, 1844.

INCORPORATION OF GENERAL PRACTITIONERS.

To the Editor of the Medical Gazette.

SIR,

IN the number of the Provincial Medical Journal for November 27th, there is a letter from Mr. Martin, of Reigate, in which that gentleman notices in favourable terms a letter I addressed to you a few weeks since (see MED. GAZ. Nov. 15th), in which I advocated the incorporation of the general practitioners. To that letter I beg leave to make a few observations in reply. In the first place, I may remark that I see nothing in the present aspect of medical affairs to lead me to suppose that any other course than the incorporation of the general practitioners can be safely advocated as an expedient measure. Did the Colleges of Physicians and Surgeons, even at this late period, show any sincere desire to admit, on an honourable and liberal footing, the general practitioners into their respective corporations as licentiates in medicine in the College of Physicians, and as licentiates in surgery (where they are not already members) in the College of Surgeons—thus creating two distinct classes in each College, fellows and licentiates; the former including all consultant and pure physicians and surgeons, and the latter including all general practitioners—I, for one, believe that the interest of the profession, as a whole, would be best met by the body of general practitioners consenting to such an arrangement. In this case the examination of the general practitioner in medicine would properly, I conceive, devolve on a mixed board, consisting of four or six physicians and as many general practitioners, the president being a surgeon. It is, however, but too probable that more exclusive views will prevail in the Colleges, and that we shall be spared the necessity of canvassing the details of any such scheme as this.

I may proceed, therefore, to consider what the plan of examination should be in case of the general practitioner being incorporated into a Society or College. I am quite disposed to admit, that when incorporated, the general practitioner should be placed in an independent position as regards the examination of candidate for the license; and that care must be taken to guard against the introduction of a “body of men,” to use Mr. Martin’s words, “less skilled and less informed than the present race of Licentiates.” Cooperation and union, however, do not necessarily imply, and indeed, may be far from implying, dependence; and I must still confess, that I should wish to see the medical part of the examination conducted by a mixed board of physicians and general

practitioners) the latter being the same individuals who assist in the medical examination,) in equal numbers, presided over by the same general practitioner, who should have the casting vote. I know that it will be urged, that there are general practitioners who, without any aid from the Colleges, are fully competent to form an examining board, both in medicine and surgery. This I am quite ready to admit, as regards medicine, to the full,—though as regards surgery, in the present condition of general practice in London, I feel a greater doubt. But if we even admit this competency to the full, I believe that the license would be much more highly valued by the candidates for it, and would be really more valuable, when attested by such signatures as those of a Watson, a Copland, a Williams, or a Forbes, in medicine; or by those of a Brodie, a Guthrie, a Cooper, or a Travers in surgery, in addition to those of learned and skilful general practitioners, than it would be if attested by general practitioners alone, however experienced, and however able. As regards surgery. I incline to believe that such a course would be essential, in order to insure a sufficient guarantee of the qualification of the candidate in this department of practice. The examiners from the Colleges would be conferring and receiving honour by such an arrangement, which would thus be alike honourable to both parties. In such a sketch as this it would be premature perhaps to attempt to fill up the details as regards the method of election, &c. which will readily suggest themselves to the reader.

There is another part of Mr. Martin's letter, in regard to which I beg to make a few remarks. Mr. Martin contends that the Court of Assistants and the Court of Examiners are distinct, and do not derive their power from the trading part of the Society of Apothecaries; and, further, that these Courts are virtual representatives of general practitioners. The Court of Examiners, I am aware, is thus distinct; but I am greatly mistaken indeed, if the Court of Assistants, by whom the Examiners are appointed, be not the ruling body of the trading company. The general practitioners of this country have received, indeed, their license to practise from the Court of Examiners, but I do not see how that constitutes the said Court the virtual representatives. They are not admitted to any participation in the government or privileges of the Society, or of the Court of Examiners; they have merely conferred on them the right to practise; and I would maintain that the general practitioners—the *great third estate of the profession in England*—are thus without either actual or virtual representatives in the medical poeity of this country. The member of the College of Surgeons has some ties,

slight and defective though they be, with the College, in the lectures, the library, and the magnificent museum of that corporation; but I am much mistaken if the licentiate of the Apothecaries' Company, after he has once received his license, ever finds his way back to the Hall in Blackfriars, unless in the capacity of a purchaser of drugs. The Court of Examiners have, however, performed their task well, and should certainly contribute a considerable quota of their number to the new examining board: indeed, in case of any charter of incorporation being granted to the general practitioners, it would only be a proper compliment to these gentlemen that such charter should be made out in their names, coupled with those of a sufficient number of the leading general practitioners, both of the metropolitan provinces of England and Wales.

It is to be hoped that, in this juncture, the general practitioners of England, will display that energy and firmness, coupled with moderation, which are calculated to secure to them that place in the medical body politic which I think they have a right to seek; and which the real interests of our profession as a whole appear to me also to demand.

I may be allowed, in conclusion, to observe, that the great danger, at the present moment, appears to me to be that of one grade of the profession seeking its own interests irrespective of those of the profession as a whole, and endeavouring to elevate itself at the expense of some other grade, whether that grade be above or below it. Let us hope that class interests will cease to be our sole principle of action, and that in this great struggle, and golden opportunity for a healthy organization of our profession, Ephraim, so to speak, will no more envy Judah, nor Judah vex Ephraim. I again take the liberty to subscribe myself simply,

MEDICUS.

IRREGULAR PRACTITIONERS.

To the Editor of the Medical Gazette.

SIR,

EVERY day brings under our notice some fresh instance of loss of life, or at least of permanent injury to health, from the practice of irregular or unlicensed persons. I was much struck on perusing a letter from Mr. W. Thompson, of Bognor, in this week's GAZETTE, detailing a case of intra-uterine hæmorrhage, where, I believe, had the patient been under the care of a medical man, instead of an ignorant midwife, her life would have been preserved.

In Dr. Ingleby's admirable work on Uterine Hæmorrhage, (I regret to say that the work is out of print, and I therefore quote

from memory), a case is narrated identical with that which Mr. Thomson has now brought under the notice of the profession. The intelligent medical practitioner who was in attendance immediately detected the cause of the alarming symptoms with which the patient was affected, and without a moment's delay ruptured the membranes, and turned the child. The patient recovered rapidly.

Had Mr. Pskett been summoned to this unfortunate woman as soon as the alarming symptoms supervened, instead of several hours being allowed to elapse, it is more than probable that a valuable life would have been preserved.—I am, sir,

Your obedient servant,

J. M. B.

Greenwich, Nov. 30, 1844.

EFFECTS OF FUSEL OIL UPON THE ANIMAL ECONOMY.

IN the course of his inquiries into effects of volatile oils upon the animal economy, Professor Mitscherlich tried the influence of this product of the vinous fermentation and distillation upon several animals. Fusel oil is a colourless oily fluid, of a most offensive odour, and very distressing to the lungs. Its taste is sharp and burning; it is lighter than water, and is composed of carbon, hydrogen, and oxygen: it burns with a very brilliant flame. A few drops of liquid albumen being thrown into Fusel oil, a gelatinous mass separates, and falls to the bottom of the vessel; a few drops of milk thrown into it, fall as a white coagulum. Applied to the lining membrane of the stomach and bowels of a rabbit just killed, the cylinder epithelium of the small intestines appears to mix with difficulty with the Fusel oil, and forms an adhesive mass, which, under the microscope, is seen to consist of extremely minute globules. The tessellated epithelium of the stomach appears to comport itself in the same way. In the experiments, the dose of poison, (5j., ij., iv., and viij.) was thrown into the stomach of the animal by means of a syringe and elastic catheter.

1st Experiment. A grey rabbit, of middling size, had 5j. of Fusel oil thrown into its stomach. Immediately, and for a short time afterwards, the animal became extremely lively, and ran rapidly about, striking itself, however, against objects in its way, without appearing to observe them. The pulsations of the heart before the injection were 132 in the minute; half an hour later, the number could not be reckoned. About ten minutes after the animal had had the Fusel oil, it became depressed, could not stand erect, and fell upon its side, in an attempt to walk, so that I thought death was imminent. The animal lay apparently with-

out motion and feeling, but when I pinched the ear, which felt very warm, as, indeed, did the whole body, the animal raised its head with a great effort, but without power to hold it up; the head immediately fell down upon the table again. The breath of the creature was at first altogether without smell, but half an hour after the injection an intense odour of Fusel oil, which proceeded from the lungs, was perceptible; a circumstance which proclaims the passage of the poison into the blood. The animal lay in the state described for two hours and three quarters, after which time, on lifting it to lay it elsewhere, I observed some slight movements; the ears were also no longer so hot; shortly after, the power of moving increased, the creature seemed to be reviving; and, by and by, having crawled to the edge of the table, it fell off. Here it lay for a while, quite still, but in a while it raised itself, and made efforts to move away; the motions, however, were all miscalculated at first, and performed in a circle: the animal then recovered its power of moving its fore feet, dragging its hind legs after it; but this seeming paralytic state soon went off, and the animal was then in a condition to move as well as ever—it recovered completely. The same experiment tried upon another rabbit produced much less decided and remarkable effects; the animal was at first extremely lively, and ran about, indeed, but shewed no symptoms of stupefaction.

Two drachms of the Fusel oil were now thrown into the stomach of a very large rabbit. The first symptoms of its affecting the economy appeared a quarter of an hour afterwards; the animal showed signs of great restlessness, and moved hither and thither, but could always sit erect. In twenty minutes it stretched its fore legs out, and sunk its head upon them; it made no motion, when I seized it by the ears, which I felt, as in the first instance, to be very hot; the pulsations of the heart were extremely rapid, and scarcely to be counted; the respirations, on the contrary, were deep and slow; the breath smelt distinctly of Fusel oil. The animal now stretched itself out, and seemed to have no power of raising its head; and so it lay for four hours, apparently without sensation and motion, the pupils dilated, the breathing heavy, and the pulse rapid. Something like convulsive motions now appeared; but, by and by, the creature recovered the power of sitting up, and next of moving at will. In the night it was seized with pretty smart diarrhoea. The animal is now quite well.

The next experiment was tried upon a lively white rabbit, of middling size, with 5j. of the Fusel oil. It soon shewed every symptom of intoxication, to which succeeded great depression: the animal could

not raise its head, the pulsations of the heart, and the breathing, which had been increased, at first became slower, and the latter laboured. The animal lay for an hour and a half without motion or sensation; the respiration becoming slower and slower, and more and more difficult. The breathing then ceased, and the animal died; the pupil being much contracted. On laying open the abdomen five hours and a half after death, an intense odour of Fusel oil was perceptible. The stomach was not altered in colour externally; it was rather white and bloodless, than otherwise. The food in the stomach was covered with a thick layer of mucus. In the fundus of the stomach there was extravasation of blood, of a dark brown colour; this dark brown matter being scraped off with the handle of the scalpel, the white surface of the epithelium was exposed, beset with small brownish red points, which penetrated to the tunica propria, from which the extravasated blood appeared to have flowed; the tunica propria itself was bloodless, and in parts soft and pulpy. The duodenum, and upper part of the jejunum, were reddened, and filled with a white mucus, made up in great part of cylinder epithelial cells; the bladder was empty. The right side of the impregnated uterus was of a scarlet red; the kidneys were healthy and bloodless; the lungs somewhat redder than usual, and crepitated little, though they swam upon water. In a fifth experiment, in which ʒij . of Fusel oil were thrown into the stomach of a large rabbit, the animal did not remain more than ten minutes able to keep itself erect, and in ten minutes more it seemed insensible to any kind of stimulus applied externally; the respiration became laboured, and the animal died within an hour. When ʒss . of the Fusel oil was injected, the animal did not live more than a quarter of an hour; and when ʒj . was used, it died in four minutes. The same experiment tried upon a dog, ʒss . being the quantity used upon a young, and not very large animal, produced the same destructive effects in the course of six hours. From the whole of the experiments, it appears that Fusel oil is a true poison: in smaller doses it affects the sensorium in a remarkable way. It is highly stimulating at first, and induces a state similar to that induced by alcohol; it then depresses signally, and throws the animal into a kind of sopor. Fusel oil affects the stomach immediately, and the rest of the system by sympathy; the great rapidity of its action seems to vouch for this: the action of the poison would be slower, had it first to be taken up in the blood. The epithelium, and the entire mucous membrane of the stomach and bowels, were found destroyed; and the tunica propria so affected, that it

could be removed with a touch. There were, besides, extravasations of blood discovered, which proceeded from the vessels of the tunica vasculosa. Fusel oil, however, is also absorbed into the system; a fact proclaimed by the smell of the breath; and it is probable that in smaller quantities the poison produces intoxication, and its other remarkable effects, through the medium of the blood.—DR. EDWARD FURST, of Berlin, in *Medicinische Zeitung*, No. 23 and 24, 1844.

PARENCESTESIS THORACIS SUCCESSFUL.

A LAD, 13 years of age, had been long ill, as I was informed, when I was summoned to his assistance. I found the boy labouring under dyspnoea of the most aggravated kind, and scarcely able, with his utmost efforts, to fetch his breath. On examining him I found the left side of the thorax greatly enlarged, and could even perceive fluctuation through the intercostal spaces. I learned that the boy had had an attack probably of pleuro-peripneumonia, which left to itself, had ended in effusion of pus. The case was pressing and admitted of no delay; I therefore proceeded at once to perform parentesis thoracis, and gave issue to three pints of bad sanguinolent matter. The patient felt himself relieved, but the breathing still continued difficult, the cough distressing, and the expectoration scanty and bad. The patient went on in this way for four weeks, hectic having been meantime set up, a large quantity of matter flowing all the while from the wound in the thorax, which the patient was himself accustomed to open in order that by facilitating the discharge, he might find greater relief. About an inch and a half under the wound, a new collection of matter began to point, which could not be discharged by the old opening. I was therefore compelled to perform parentesis again in this new situation, after which the superior wound closed. The discharge from the new opening was at first great, and continued so for a long time, but then gradually began to diminish. The patient recovered his appetite under the use of a gentle restorative plan; he was at length restored to perfect health, and has remained well ever since.—DR. THORSTON, *Medicinische Zeitung*, No. 30, 1844.

FRIDAY, JANUARY 3, 1845.

CASES TREATED IN THE WESTMINSTER HOSPITAL

BY BENJAMIN PHILLIPS, F.R.S.
Assistant Surgeon.

Lock Jaw.—Tumor of the Jaw.

LOUISA RUSSELL, aged eighteen, was admitted into the Westminster Hospital, July 25th, under the care of Mr. White. She was a housemaid, and the account she gave of the attack was, that while eating of a mutton chop with her tea, she suddenly felt great stiffness about the mouth and throat, and a sensation as if a portion of the meat was wedged in the throat. After some efforts to relieve herself, she proceeded to the Hospital, complaining principally of the inconvenience in the throat. The house-surgeon desired her to open her mouth to enable him to make the necessary examination, when he discovered that the jaw was closely locked. An Enema of Opium and Assafoetida was administered, and the next day she was seen by Mr. Phillips.

Her state at that time was described in the following terms. The patient, a very healthy young woman, has the jaw firmly closed, the muscles about the pharynx rigid, and those at the back of the neck tense, and somewhat painful; the expression of the face is placid, the pulse is quiet, and the respiration natural; the abdomen is tense and tympanitic, but there is no tenderness at any point. She states that she has no headache, that she has never been ill, that she has never experienced any hysterical feelings, or cramp; that the menstrual functions have been discharged with regularity, but that the bowels have always been sluggish. There was no wound on the surface, and she could not recollect that she had received any injury of any kind, and there was no mental disquiet. After a very careful examination of the circumstances, Mr. Phillips

came to the conclusion that the attack was probably of an hysterical character.

He directed that the bowels should be stimulated by irritant injections, and that a large dose of Calomel should be got upon the tongue.

July 26th.—Enema Terebinthinæ statim.
Hydrarg. Chloridi, gr. vj.

On the evening of the day after the action of the enema, and about thirty-two hours after the development of the trismus, she fell asleep, and when next seen by the house-surgeon the jaw was relaxed. Soon after this she awoke, and then the trismus was reproduced, but by morning it had yielded again.

27th.—At the hour of visit, the spasm is less marked than it was yesterday. The muscles of the jaw are less tense, the mouth can be opened sufficiently to allow of the tongue being protruded: the muscles of the pharynx are less rigid, and the tension of those at the back is much abated. The pulse is 82.

The bowels have acted freely, but the evacuations have been offensive; there is less distension and tympanitis.

To have another Turpentine Enema, and to take ʒj. doses of Tinct. Valer. Ammon.

28th.—The trismus has entirely ceased; during the last twenty-four hours, however, it recurred twice, but it was slight, and soon disappeared. She is now free from any spasmodic action, but there is still a fulness of the abdomen.

To take Hydrarg. Chlor. gr. ij.; Pil. Galb. Co. gr. v. at bed-time; and an aperient draught in the morning.

From this time she was convalescent.

30th.—She complained of soreness in the throat low down; a sensation as if something were lodged there. Nothing could be discerned, but on several occasions a little grumous matter was spit up.

She remained in the hospital until that inconvenience disappeared, and her bowels had been got into a less sluggish state; when she was discharged, cured.

REMARKS.—When Mr. Phillips saw the case, he conceived it to be hysterical; the treatment was based on that opinion, and the result seemed to justify the conclusion.

The absence of any injury, of mental discomfort, or exposure to cold, and the suddenness and completeness of the lock jaw, together with the age of the patient, determined the opinion; at the same time there was no clear evidence of any previous hysterical condition, and the general health was apparently very good; the uterine functions were regularly performed. The occurrence of lock jaw in the absence of a wound, or other injury, is comparatively rare, but so varied and singular are the features of hysteria, that there is scarcely any disease which it may not simulate. Mr. Phillips mentioned a case which he observed some years ago, where amaurosis of the left eye occurred as a consequence of an injury to the left radial nerve; it persisted for several weeks, and then suddenly vanished. He also mentioned a case which occurred to him a week or two previous to the preceding case, and which he believed to be hysterical.

A young woman who on the previous night had taken a colocynth pill, went to the water closet, where she remained long enough to cause alarm. Calls at the door were unheeded, and it was forcibly opened, when she was found leaning back insensible. She was immediately removed to a bed; salvolatile was administered, and a certain amount of consciousness returned. She evidently comprehended all that was said to her, and attempted to answer questions, but all her efforts ended in the utterance of inarticulate sounds, although she could project the tongue in a right line. After many such attempts she became a good deal distressed, and a paroxysm of crying followed. Upon further examination it was discovered that there was complete dextral hemiplegia. It was treated as hysteria; mustard was applied to the epigastrium, and drastic purgatives, with antispasmodics, were exhibited internally. Within two hours she could use the right leg; within four hours speech was restored; but the natural functions of the hand were not restored for more than a week. It is possible, of course, that the preceding case was something more than hysteria. The mode of its occurrence might lead to such a conclusion; but the result seems to lead to the impression that the original view of the case was correct.

With respect to the case of lock-jaw, thirty-two hours had scarcely elapsed before

the spasm was completely relaxed, but after that there were two slight relapses.

It was suggested by Mr. White, that from the mode in which the spasm occurred, there might have been some jar or strain upon the pterygoid, or some other muscles of the jaw, so as to produce cramp. Of course such a thing may be possible, but although such jars must be common, we are not aware of any case which acknowledges such a cause. There was no reason to think, either, that she suffered from worms, which have been by some persons regarded as occasional causes of tetanus; and beyond what has been stated, there was no circumstance present to throw any additional light upon the cause of the attack.

Mary B., æt. 24, a widow, was admitted under the care of Mr. White, July 16, 1844, with a tumor of the lower jaw extending through the space which had been occupied by the bicuspid and two molar teeth of the right side.

She states, that about three years ago, she suffered very much from what she supposed to be toothache, and that three teeth had been removed for the purpose of giving relief. Still the pain continued. After a time, however, it gradually abated. About a year after the extraction of the teeth she first became sensible of a swelling of the jaw; it slowly increased without much pain, except at night, when she was often kept awake by its severity.

A variety of remedies had been used for the purpose of checking its increase, but without effect, when she was told that the only thing that could be done for her was to remove so much of the jaw as was implicated in the disease. After this she was admitted into the Winchester Hospital; but after a time discharged without relief. On examination after her admission into the Westminster Hospital, a tumor was found extending from the canine tooth backward as far as the last molar, and projecting towards the cheek externally, and slightly pushing aside the tongue internally. The tumor gives her very little uneasiness during the day, but it is painful at night. Her general health is good, and she is very willing to submit to any means of relief that may be recommended.

A consultation was held upon her case, and it was agreed that the only plan of treatment which promised success was to remove so much of the jaw as was implicated in the disease.

On the Saturday after her admission, Mr. Phillips proceeded to operate in the following way. An incision was made from the angle of the mouth to the inferior border of the lower jaw, and terminating about an

inch from the symphysis. Another incision extended along the inferior border of the jaw, from a line in front of the facial artery, to form a junction with the first incision. The flap was turned back and retained by an assistant. The soft parts were then cut through to the bone at the two points upon which the saw was to be applied.

A very ingenious circular saw was used to cut through the bone; what remained was broken down by the forceps, and the piece, which included the entire thickness of the jaw, was removed without difficulty. The flap was then laid down and scoured by a single point, but the wound was not definitively brought together till the evening.

There was not much hæmorrhage, and the patient bore the operation well. It occupied about five minutes in the performance. The sutures were removed on the third day, with the exception of one; the greater part of the wound being united. The only part in which adhesion had not taken place was a small point near the masseter muscle. The case did very well, and at the expiration of six weeks the patient left the hospital well, with scarcely any appearance of deformity, and able to masticate soft substances. The space between the cut extremities of the bones seemed to have lessened a good deal since the operation, and there was a dense substance developed between them.

REMARKS.—The appearance of the tumor in this case, as well as the history, induced Mr. Phillips to regard this as a case of epulis. The only point calculated to cause any doubt of its nature was the very regular fusiform character of the enlargement. The soft parts, however, were unaffected, and there did not appear to be any thing to militate against the operation. It was therefore performed, and was well borne by the patient. A piece of the jaw, including its entire thickness, and somewhat under two inches long, was removed. Upon examination it presented a central softening, and a good deal of the character of osteo-sarcoma.

The case did remarkably well, and by the fifth week a tolerably dense fibrous mass connected the cut portions together, and enabled her at that early period to masticate soft substances.

An opportunity was presented for examining a jaw from which Mr. Phillips had removed a similar piece of bone two years before. The patient was between fifty and sixty, and the connecting medium appeared to be almost as dense as bone. He could masticate the hardest food, and could even crack a nut on that side.

SOME OBSERVATIONS

ON THE

MEDICAL TOPOGRAPHY, CLIMATE, AND DISEASES, OF THE BIGHTS OF BENIN AND BIAFRA, WEST COAST OF AFRICA.

BY W. F. DANIELL,

Member of the Royal College of Surgeons of
England, &c.

(For the Medical Gazette.)

Χωρέων δὲ θέσιν καὶ φύσιν ἐκάστων ὠδεῶν διὰ γινώσκειν.—'ΙΠΠΟΚ. περὶ Διαιτήης, β.

WHEN we refer to the annals of history, we find that the Portuguese and Spaniards were from a very early period familiarly acquainted with the greater portion of the western coast of Africa. They appear to have been uniformly actuated by the narrow-minded policy of the adventurers of that age, and indeed of much later ages; they neglected no precaution whereby they might secure to themselves the rich field of commerce, which was there displayed to their admiring gaze, and used every means to exclude other nations from partaking in its varied resources. A few years, however, must have demonstrated the fallacy of these expectations, for we find in the year 1553, records of an Englishman, of the name of Wyndham, trading in the Rio Formosa for pepper, and other indigenous productions, in conjunction with a vessel belonging to the Portuguese. From this period, British influence may be said to have gradually extended itself over the Babel of petty kingdoms that stud the shores of Western Africa, from the Gambia to the equator, and from thence to the Cape of Good Hope; the supremacy, trade, and prospects of earlier discoverers, waning rapidly under the influence of successful rivalry.

A glance at the mercantile relations of Great Britain with this portion of Africa, will shew how extensive and important the connexion has become, especially since the commencement of the present century. Were it not for the fatal insalubrity of climate, so destructive to the European constitution, where life is not forfeited at once, it is impossible to say what extent our commercial intercourse would have acquired with the inland regions of the vast continent of Africa, which lie at this moment unexplored and unknown. The

rivers which empty themselves in the Bights of Benin and Biafra nevertheless receive from sixty to seventy vessels of considerable burden annually, which employ several hundred seamen, and, carrying out freights of the manufactures of this country, return with cargoes of palm oil, ivory, dye-woods, and other articles of price.

Although this portion of the coast of Africa is so much frequented, and so large a quantity of its produce is transmitted year after year to English ports, it is surprising how little information we have relative to its topography, seasons, capabilities, natural productions, inhabitants, &c. This, however, may in some measure be owing to the individuals who visit that country being rarely possessed of the kind of education which he who travels into new and little known regions ought to have, and partly also because it is not always held prudent among trading communities to promulgate information which might possibly conjure up a host of competitors. And then it is certain that in many instances those who were most competent to give information upon the countries of Central Africa have been the victims of its unhealthy climate.

It is much to be regretted that the causes of the insalubrity of Western Africa, and the pathology of its maladies, should be so imperfectly understood at the present time, since the preservation of life ought surely, above all others, to have been made the subject of most serious consideration.

During my residence in several of the rivers which form what is termed the delta of the Niger, and when anxiously engaged in my professional duties, I have often painfully felt the necessity of a work of reference which might throw some light on the disorders that were endemic in those districts, but I must confess that I have found nothing to aid my investigations on this important subject. This hiatus I have now essayed to fill up by the few succeeding hasty and, I fear, imperfect sketches. I am fully aware of the deficiencies that must almost necessarily be apparent in them, but I trust that the motives which have led me to come before the profession will plead in some degree for all imperfections of style that may appear, and that the facts and observations I have to offer

may contribute to the benefit of those who are obliged to visit the coast of Africa. I shall also enter at some length into the host of pestilential diseases which there prevail, and which prove at periods far beyond the control and best efforts of human skill. Had it not been for the confidence inspired by a practice successful in the great majority of cases, my inclinations would have prompted me to let the subject fall into other hands more competent to discharge what I believe to be an imperative duty.

In referring to the publications which have appeared during my absence from England, I accidentally met with a series of papers on the fevers of the Gambia and Sierra Leone; since my return I have also perused the work of Mr. Boyle, which I had not done previously. The papers on fever by Dr. Burton, communicated in the *Provincial Medical Journal* for 1842, certainly afford the most correct and comprehensive delineation of the affections endemic to our African colonies; and many of his views are in perfect accordance with my own, while others are greatly at variance. Of course, considerable allowance must be made for differences of situation, geological distinctions, and the circumstances under which he has studied African fever. Circumstances always essentially modify the characters of tropical diseases. It may be also necessary to state, that although a remarkable coincidence frequently occurs in the mode of treatment between Dr. Burton and myself, yet I was thoroughly convinced, from practical experience several years before the appearance of his sentiments, that the means I had adopted were the most efficacious that could be used. More recently, and since the preceding passages were written, the *Medical Reports of the Niger Expedition*, by Drs. McWilliam and Pritchett, have been published.

Although the diseases which prevail on the west coast of Africa may be considered as but few in number when placed in contrast with the more varied and comprehensive series of European maladies, yet they are not the less entitled to our attentive consideration: in point of interest there is, perhaps, no class of morbid affections to which the human frame

is liable which demands greater attention, or requires a more studious investigation, than those of which I am about to treat. At present, little progress has been made in the ample field of pathological science presented by the African continent; it is only recently that the few works which profess to allude to the subject have appeared, and they, like all rudimental treatises, afford but very partial general summaries, the principal object proposed being usually little more than a meagre description of those diseases which are prevalent in our colonial settlements in the higher latitudes of this continent; the lower, or equatorial division of the coast, being left entirely uninvestigated.

Experience has already demonstrated the fact that of all those tropical countries visited by Europeans, Africa is that which is most deadly. The humidity of its atmosphere, and the high range of temperature, conjoined apparently with exhalations due to the decomposition of vegetable matter, conspire to render it singularly inimical to European constitutions, and to make it the theatre of a class of diseases differing from any that have been observed in other quarters of the globe.

NOTICE

OF

THE MEDICAL ORGANIZATION, STUDIES, &c. IN ITALY.

By EDWIN LEE, Esq.

(For the *Medical Gazette*.)

[Continued from p. 352.]

Universities.

CONSIDERED in an abstract point of view, each university presents itself to the observer under a twofold aspect—as an academical body charged to watch over the progress of science, and as an instructing body occupied in diffusing knowledge according as the populations are adapted to receive it. At Genoa, and at Turin, a supreme direction of public instruction, termed *Magistrature della riforma*: in Tuscany, a college of Doctors; in Lombardy, an Aulic Councillor, directly commissioned from the Governor of Vienna: at Rome, the *Sacra congregazione degli studi*, with an Arch-Chancellor at its head: at Naples, a Junta, presided over by an

archbishop: at Parma, and at Modena, a Grand-Master: such are the authorities which bind the universities in Italy to the government. Being purely moral or political, they offer, in this respect, a great difference with the Royal Council of Public Instruction in France, which is composed of men purely special: their office, as stated in the ancient and modern regulations, consists, as is expressed in those of Turin, in taking care that nothing is publicly taught but sound doctrines, not opposed to religion, to the rights of the King, or of the Crown: hence with them rests the appointment of professors and the direction of the studies. Primary, secondary, and superior instruction—all is dependent upon them. The members of these institutions have never themselves belonged to the professorate; not one of them is a theologian, jurisconsult, physician, or mathematician, in the strict acceptation of the term*.

At Genoa and Turin, the chief president of the reform may be truly regarded as the minister of public instruction. He receives his orders directly from the King; these are transmitted by brevet, by letters patent, or *vivavoce*: in the two former instances, they are countersigned by the minister of the interior. In other parts of Italy the President of the Commission of Instruction works with the head of the state; but as the President (a worthy representative of the commission itself) does not possess special knowledge sufficient to consider the wants of instruction in a practical point of view, these are for a long time passed over, or badly understood; the position of the professors does not appear to be sufficiently elevated for them to be called to take part in the direction of matters of which they ought to be the legitimate judges. The members of

* This may be the case in some states, but it is denied by Professor de Renzi with respect to Naples, where the Junta of Public Instruction has not merely the mission of superintendence of public *morale*, but has the care and direction of the studies, and proposes to Government the requisite reformatations or alterations of the course of instruction. Its members are selected from among the professors of the different faculties, those being preferred who are distinguished by talent, probity, long experience, and public approbation. Hence the Junta is composed of theologians, jurisconsults, physicians, mathematicians, and *letterati*, and cannot be liable to the abuses indicated by M. Combes; being, in fact, very analogous to the French Council of Public Instruction.

the Grand Council of Studies belong to the higher orders of society*. A name is required for them, rather than talent and experience. What has been said of the directing principle of the Italian universities is applicable in great measure to their purely professional character, which varies in different countries; for although each university usually comprises four divisions, viz. theology, law, medicine, and the belles lettres, there are some (as at Pavia) in which the first of these faculties is not joined to the other three, inasmuch as in Lombardy the political is separated from the religious powers in some respects: on the other hand, at Genoa, Modena, Rome, the Catholic authority and instruction predominate; while in Tuscany, the different branches of the healing art have an evident supremacy. In the University of Genoa the faculty of medicine and surgery ranks after the faculties of theology and jurisprudence; its doctors, masters, members of colleges, or professors, hold a subordinate position in society. Restricted within the limits of their humble and but little lucrative condition, none are called to fill public offices unless immediately within their speciality. It was regarded as a circumstance without precedent, and as a phenomenon, that Dr. Scassi, who was *prefet* of Savona under the empire, should have obtained, in 1814, the title of count, and should have been appointed syndic of the city of Genoa.

Is it sufficiently known what are the results of this state of things, and the consequences of the low estimation in which an entire class of the population is held? Is it not perceived that this class isolates itself from the rest, and that all its habits and acts form a continual protest? Thus, when an extraordinary danger presents itself, or when it becomes a question to make head against a common enemy, or one of those circumstances occurs in which honour alone can retain men at their post—as a disastrous epidemic, a pestilential fever—the physicians will refuse to join themselves to those who would not admit them within the pale of social fraternity. For this reason the greater number of the Genoese prac-

titioners left the city on the invasion of the cholera.

The divisions generally adopted in instruction are, anatomy, physiology, pathology, practical medicine, surgery, *materia medica*, medical jurisprudence, and hygiene; to which are added, as accessory, chemistry, medical physics, natural history, and pharmacology; thus forming twelve professorships. In Italy this number is in some places greater; in others it is less: thus in Piedmont and in Tuscany the faculty of medicine has only ten professorships; in Rome and Bologna there are eleven; fifteen at Pavia; and eighteen at Naples. At Florence and Pisa descriptive anatomy is subdivided into human and comparative anatomy; and at Pavia microscopic anatomy is added. In the latter city, as also at Naples, theoretical and practical ophthalmology are joined to surgery. In the faculties of the Austrian States, and in Tuscany, the principles of the veterinary art are taught. Here, likewise, is a professor for the history of medicine.

In many towns of Italy there are secondary schools of medicine, but they have not the same degree of importance as in France, and their courses of instruction are very circumscribed. In some parts, more especially in Tuscany, the theoretical studies are separated from the practical. The examinations take place at Pisa and at Sienna, where the title of Doctor is conferred; but the clinics are at Florence, and these must be followed two years before the *exerceat* is granted. Lectures on other branches are also given at Florence, as well as the clinical courses in the hospital of Santa Maria Nuova.

Of the different examinations required in a faculty of medicine in Italy, one alone is public; viz. that of the discussion on the thesis, to which the same form is given as in the French schools, except at Bologna, at Rome, and at Modena, where it consists in a simple programme of questions without any dissertation. All the other trials take place with closed doors, before four examiners and a president, who has the casting vote, but does not examine. Each professor examines upon the subject-matter of his course, the questions being drawn by the secretary. The examination takes place in the Latin language. Each

* This is not the case at Naples.

examination lasts three hours; at the expiration of which the candidate retires previous to the formality of admission or rejection; to decide upon which each examiner has three balls, a white, a red, and a black one. The first represents three favourable points, the second two, the black ball signifies only a negative vote. Ten points are required for the admission of the candidate. If the number be less than this, his rejection is pronounced: this frequently occurs, and the rejected student is adjourned (*aggiornato*) for a year. In Piedmont a second rejection incapacitates the candidate from again presenting himself for examination.

At Genoa the circumstances connected with the admission to the doctorate deserve to be noticed.

The candidate receives a series of questions, which he is not required to develop, but contents himself with studying and meditating upon them, in order to maintain them on a fixed day before the doctors of the college charged with the augmentation, as also before an unlimited number of the professors, who, however, take no part in the discussion, but have the right of voting. The candidate is considered as the representative of the doctrines in which he has been instructed, and is accompanied by his master, who is termed the *promotore*, and assists in the discussion, taking the candidate under his patronage. When the discussions are over, and the candidate is admitted, the *promotore* makes an oration in his praise, reminds him of the duties, and, investing him with the emblems of his new condition, reads to him the form of the required oath, which the new doctor repeats upon his knees. The faculty of Montpellier proceeded much in the same manner before 1830; and notwithstanding the criticisms of the *promotore*, this imposing ceremony, it is asserted, exercised great influence on the future career of many individuals.

A glance at the names of the authors of the works recommended to Italian students may serve as a means of estimating the condition of medical doctrines in this country. In the accessory sciences and surgery, there are but few authors of note in Italy; not but that there are celebrated chemists, naturalists, and surgeons, but in this respect Italy is much inferior to France, which abounds with distinguished

names in these departments; whereas in Italy these form rare exceptions to the generality. Hence in all the courses of chemistry beyond the Alps, the names of Thenard and Orfila are frequently heard; their works form the text-books of the classes, and are in all the libraries, and their busts adorn many laboratories. The names of Gay-Lussac, Prevost, and Dumas, may also be cited, though their books are restricted to a more limited circle of readers. Orfila is almost exclusively quoted in toxicology. In botany, the names of Linnæus, Jussieu, Decandolle, and Mirbel, are those most frequently cited.

With respect to surgery, the superiority of France is also not to be contrasted; Sabatier, Boyer, Dupuytren, Delpech, Velpeau, Roche, and Sanson, with several others, constitute the ordinary guides of Italian students. The same also holds good in great measure with regard to obstetrics.

In medicine, properly so called, a contrary tendency is observed. The influence of the different French schools, and of the systems of their chiefs, is less experienced. The predominating principles are derived from Germany, except in those instances where they originate from Italians. Thus, physiology has derived a great impulsion from the ideas of Gallini, Tommasini, and Medici: thus internal pathology, practical medicine, and the clinics, are divided into two parties; in the one, the study of the works of Rasori and Tommasini are recommended, and their doctrinal supremacy is extolled; in the other, the ancients are the only models for imitation; as Baglivi, Sydenham, Torti, Stoll, &c.: and nearer to our own times, the German celebrities, with P. Frank, (formerly professor at Pavia) at their head; G. Frank, his son, Hartmann, Hildebrand, Raimann, and lastly, the best known among the Italian physicians of the present day, Buffalini, and Paccinotti. The organical classifications, as adopted a few years ago in France, are not reproduced in the public lectures; Andral is the French pathologist most in repute among the Italians; in fact, his doctrines serve as an intermedium between the pure vitalists and the anatomopathologists—joining that which was to that which is. Foreigners, however, are apt to fall into a great

error, in regarding as the sole representatives of French medicine one or two celebrated names, and in thinking that this is entirely restricted to Paris. Doubtless the greater number of works relating to the healing art are accumulated most easily in the capital, by the fact of its being the point of scientific centralization; but these works are far from being homogeneous; and what a vast difference, for instance, separates MM. Bouillaud, Bisseau, and Andral, on the one hand, from MM. Chomel, Cayol, and Recamier, on the other. In other parts there are likewise to be found acute and faithful observers, as also powerful minds, profound generalizers, having each their peculiar individuality. In the same sense perhaps it might be said that Rasori represented Italian medicine.

The most ancient trace of the organisation of universities in Italy is to be found in the denomination of the different grades. Thus, at Pavia, that type of the ancient universities, a man who possesses the title of rector, rector magnificus, has the direction of the studies, and the superintendence of the *personel*. The same rank also exists in Piedmont, and is directly conferred by the king: at Rome a rector is appointed by a delegation of the college of consistorial advocates, and is confirmed by the pope, whereas at Naples this office is about to be superseded by that of the President of the Central Commission; and at Parma, there are substituted for it four *Priori*, each having the superintendence of a faculty. In Tuscany, after the Prince, there exists a sub-intendent, a purely administrative functionary, who is represented at the head of the different faculties by a *Preposto*, who is usually selected, like the rectors, from the professors, who, however, take no part in his election. He holds the office for one or two years, as in Lombardy, where there are, besides, an Academic Councillor, the Director of the Studies, the Deans of the Faculties, after whom come the Professors.

It may be boldly affirmed, that, in general, Italy has not bestowed upon these latter any of those honours formerly so prodigally lavished upon her poets, painters, musicians, and sculptors; abased almost to the rank of simple handicrafts, regarded as men who make a trade of science, the members

of the faculties are but little esteemed in the world—at least as such. In Piedmont, the professorship is acquired without competition; the king appoints an individual on the presentation of the supreme delegation of the studies, which may afterwards displace the person whom it has caused to be nominated; no guarantee is previously given to the professors, no legal protection is assured to them; they exist entirely dependent upon the good pleasure of others, without any resource against injustice. Such a position is more painful, more precarious, and uncertain, than that which is said to have been the lot of public functionaries in France at the time of the great revolution.

The following is the mode in which professors are nominated in Lombardy:—

When a chair becomes vacant the Austrian governor is informed of it. Immediately the Proto-medico of Vienna transmits a series of questions, which are placed beneath the eyes of the candidates. When these are answered with all the precautions indicated by the *concours*, isolation, surveillance, a fixed period, &c., they are sent to the university (Pavia, or Padua) where the vacancy does not exist, with an epigraph, or other conventional sign attached to each memoir, in order that the author may remain unknown to the judges, who pronounce their decision on the memoirs, and class them according to their merit: the names of the three first candidates thus recommended are submitted for the royal sanction, and there is not an instance of the person whose superiority has been declared by the university decision not obtaining the vacant post.

The salary of professors in the schools of medicine in Italy varies greatly. In some faculties it amounts to upwards of 5000 francs, whereas in others it is not more than 500 or 600. In Pavia, the three professors of clinical medicine, clinical surgery, and general pathology, receive each 5000 francs a year; the professors of obstetrics, chemistry, special therapeutics, ophthalmology, human anatomy, and physiology, have 4600 francs; those of natural history, or of medical jurisprudence, 3900 francs; those of botany, and the veterinary art, 2600. At Genoa the profes-

sors of medicine and surgery receive a fixed salary of 1333 francs; a sum of 600 francs is granted in addition to the professors of clinical medicine, anatomy, and materia medica, for the right of examination; the other professors have somewhat less for the same right. Each professor has a retiring pension, after fourteen years' service, equivalent to half his salary; this is increased a fourteenth every year, so that in the twentieth year it amounts to the original sum: this plan has the advantage that when an individual is advanced in life he has no interest in occupying a post to which his powers may be unequal.

At Naples, the professors of all the faculties have an equal salary; for the first year, 400 ducats salary, and 200 gratification, (total 2600 francs); in the second year the salary is increased by 100 ducats: the directors of the clinics and of the cabinets have besides 400 ducats a year.

In the university of Naples there exists a dean for each of the five faculties. His office lasts two years. The college of deans consists in the meeting of the whole five, for the purpose of proposing improvements in the courses of instruction, and for the maintaining the discipline and general regulations. This college examines every three months whether any abuses have been introduced into any part of the service. At the head of the university is a rector, chosen from among the professors, and holding the appointment for two years. He presides over the college of deans, watches that the professors perform their duties, prevents and rectifies disorders, is present at examinations, keeps the great seal of the university, which he represents upon public occasions, convokes the faculties for the examinations, and receives the oaths of those who are admitted members of the faculties. He is, moreover, bound to render a strict account of the university to the President of Public Instruction.*

Professors in Italy, when absent, or from other causes incapacitated for a time from performing their duties, are supplied with a substitute, who in Lombardy is selected by the professor from a list of three names, and the nomination is confirmed in Vienna; the office being held for a year, or at most two years. In the Pontifical States, each

faculty has a substitute attached to it that of Jurisprudence has, however; two; they are elected by concours, and have a legal right to the first chair vacant in the faculty to which they belong. In Naples, each professor has his substitute, who is elected by means of public competition (concours), which is as severe as that for the professorship; they receive some compensation, and their title gives them the preference in the concours for the office of professor. In some places, when a professor cannot continue his lectures, intimation of the circumstance is sent to the substitute by the Prefect of the Studies, who notifies to him the method which he is to follow, as established by the professor whom he represents. Thus he is obliged to restrict himself to a mere repetition of the text of another. This inferior grade of the instructing body is not merely established for the purpose of providing against an interruption of the courses, but is sometimes, as in Piedmont, and in Tuscany, charged with the examinations; and this, in point of fact, is the proper office of the College of Doctors, who are analogous in some respects to the *agregés* of the French faculty; but their rights are more restricted, and they are not allowed to give private courses of lectures. The doctors of the college are eighteen in number; twelve doctors of medicine, and six doctors in surgery. The possession of a diploma, and a certificate of two years' private practice, are the conditions which give a claim to admission as a doctor of the college; the selection from the claimants depending upon the other titles which they may possess—the works they have published, or the services which they have rendered, of the value of which the supreme deputation of studies usually pronounces on the attestation and warrant of the professors. In some instances, however, the king directly appoints individuals as members of the College; thus Doctors Viviani, Silvestri, and Campanella, were admitted into the College at Genoa as a compensation for their services during the cholera.

From what has preceded, it may be perceived that in Italy elections in the instructing bodies are determined more or less by the method of concours. At Naples, the archbishop, in his project of reform, has proposed a new combi-

* Professor de Renzi's notes.

nation of the two methods (concours and nomination); viz. the opening of one of these scientific contests in all cases in which the estimation of the titles of a candidate would not evidently entitle him to be nominated at once. In every other case a marked tendency exists for the adoption of this mode of election in its most absolute sense.

The concours, it is said, prevents the entrance into the list of candidates of men of real and recognised merit, especially if they have arrived at a certain age, because such would not enter into a contest with young men without fixed position or reputation, and who have nothing to lose by failure.

To proclaim the concours as a perfect institution is to accord it a merit which no one would grant it; consequently one need not be surprised that its warmest partisans admit the abuses which may accompany it; and the valid grounds of some objections, as, for instance, that above cited; but, on the other hand, what advantages does it not present? Foremost among these advantages may be mentioned the consecration of the principle of equality before the law, which principle has its application in the present instance by the admission of all those who possess a diploma; each individual in this manner, alone, and without any other protection than his personal merit, without any other support than the confidence which a well-followed course of studies supplies, has afforded to him the opportunity of coming before the public, and making himself known; whereas, if this opportunity were lost, he would have remained unknown and lost among the crowd. On the other hand, the trials should impose the obligations of exhibiting spontaneity or erudition, which two-fold end is obtained by means of improvised discourses and writings.* It may be said that a facility of language, (that sort of *prestige* which cannot be sufficiently guarded against) would often enable ignorant but audacious presumption to silence and eclipse modest and timid erudition: and this reproach might be allowed to be just, if the persons called upon to

judge upon the respective merits were not by their position guarded from the influence of a similar seduction. Those accustomed to the practice of teaching, being obliged every day to give to things a higher value than that of words, are readily able to discern in a candidate the groundwork and the form; the intimate knowledge, and the manner; the principal and the accessory. Hence, there is no fear of their being deceived, because none better than they know how to distinguish between the readiness in speaking, the habit of expressing without logic or synthetical ideas, from the ready eloquence which is the consequence of a good method of philosophising.

It would, however, be wrong to undervalue the power of language, as regards teaching: here, it is not sufficient to know, but it is likewise requisite to be able to explain the ideas, and to divulge the knowledge acquired in the silence of the closet; and how can the best informed fulfil this condition, if he does not possess the full gift of speech? This likewise applies to the precious faculty of expressing one's thoughts with the pen; a professor should possess some of the qualities of the literary man:—the phrase of Buffon, *the style shews the man*, is specially applicable to him; the written proofs of the concours indicate beforehand the form which the professor would give to his lectures, at the same time that they supply a manifest evidence of his intelligence and erudition. All these advantages are united on the occasion of the thesis, which is also a solemn circumstance in which the candidate shows himself in the fulness of his individuality, and in which is revealed his mode of thinking, speaking, and writing.

There only remains to reply to the objection that youth may deter those of maturer age from offering themselves; that rising talent may eclipse merit in its force and power. These assertions are partly true; hence they must be taken into consideration, but as exceptions, and only because in every case the exception confirms the rule.

It will be readily understood that some scientific and celebrated characters would not risk themselves in the honourable, but always difficult trial,

* The author has not sufficiently reflected that this kind of trial does not well resolve the problem, whether the candidate makes an exhibition purely of *memory* or of *knowledge*.—Note of Translator.

of the concours, and expose themselves to the uncertainty of the result to which it may give rise.

It must also be remembered that eminent men, these exceptional persons, are produced much more easily when they already belong to public instruction: the professorship, in procuring for them a higher reputation, impresses upon them the duty of increased knowledge, and greater obligations; publicity becomes at the same time a guarantee and a means of emulation.

The following are among the propositions made on the subject of elections by Signor G. Mazetti, President of the Public Instruction at Naples:—

“The titles in virtue of which professorships might be directly conferred, shall be—1st, the works, and the productions which have been received favourably by the public, or approved by some celebrated Academy; 2d, a service relating to instruction, in which proof has been given of knowledge and zeal; 3rd, the trials of a former concours for a professorship of the university; 4th, literary avocations exercised honourably and ably in the public service.

“When a chair becomes vacant in the royal university, the President of Public Instruction shall announce, by means of advertisements in the Journals, and at the University, that the selection is about to be made, in order that each candidate should send in his name and claims within the given period.

“The candidates’ names having been collected, the president, and the commission charged to pronounce upon their morality, shall examine the claims of each, according to the preceding regulation; they shall then make a list of those who are eligible to be presented to the minister and to the king, indicating opposite each name the chief reason of their choice.

“If his majesty should not think proper to appoint any of the persons proposed, the concours shall be opened, to which the proper candidates shall be admitted.”

[To be continued.]

THE PERIODICAL MATURATION AND EXTRUSION OF OVA, INDEPENDENTLY OF COITUS, IN MAMMALIA AND MAN,

PROVED TO BE

THE

PRIMARY CONDITION TO THEIR PROPAGATION.

By TH. L. W. BISCHOFF,

Professor of Medicine, and Director of the Physiological Institute at Giessen, &c. &c.

To the Editor of the Medical Gazette.

SIR,

THE accompanying is part (about a fourth) of an essay from the pen of Professor Bischoff, of Giessen, late of Heidelberg) the importance of which struck me on my first receipt of it from my friend, the author, in the commencement of the past summer, and which I then formed the intention to translate. Should you rate its importance in a physiological and medico-legal point of view as highly as I am led to do, and consider it desirable for the MEDICAL GAZETTE, I shall feel great pleasure in furnishing you with the remaining portion.

I am, sir,

Your obedient servant,

HENRY SMITH,

Fellow of the Royal College of Surgeons, and Surgeon to the Royal General Dispensary.

17, Henrietta Street, Cavendish Square,
Dec. 21, 1844.

Whoever occupies himself with the history of the various theories of generation must quickly perceive the foundation of most of the errors in that department to be, and to have been, without doubt, a want of acquaintance with the primary formative material for the future being, the ovum, and its pre-existence in the ovary, entirely independent of coitus in mammalia and man, which have engaged the greatest share of interest. This necessarily induced a distinction and a gap of separation between mammalia and man on the one side, and the rest of the animal kingdom on the other, which, indeed, many observers endeavoured to repair and fill up; but the importance and necessity of objective information presented themselves with such force, that for this very reason the greatest and most illustrious authorities remained in doubt and error. There are probably few subjects which prove the dependence of human knowledge upon objective investigation in a more striking man-

ner than that which is now in question. Philosophers, theologians, doctors, and naturalists of every country, have laboured to overleap this little deficiency of the objective proof of the ovum in mammalia and man, and all their speculative cogitation, all their combinations and theories, led them into obscurity. All the world became firmly convinced that mammalia and man formed an exception to the mode of development of the rest of organized beings, and to the conditions to which they are subject.

We observe universally with respect to other animals and to plants, that, with proportionately very few exceptions, their propagation is so conditioned, that the older primitive organisms produce certain materials, ova and fecundating material, from the reciprocal influence of which upon each other, the germ, endued with the capacity of development, (*entwicklungsfähig*) results. At the same time, we further observe, as an universal rule, that the formation and coming into contact of these two generative materials, however necessary both may be for the maintenance of the species, are nevertheless quite independent of, and, in reference to each other, for the most part quite accidental. The ova form, and become mature, and are extruded from the maternal organism usually at fixed periods, having regularly recurring intervals, quite independently of the formation and maturation of the fecundating material in the male, which takes place either in like manner periodically, or even continuously. By the operation of accessory circumstances dependent on external causes, and which may either arise absolutely from without, and be entirely accidental, or may be caused by certain vital phenomena simultaneously developed in some other manner, both materials are brought into connexion with each other, and thereby the germs rendered capable of development. Should these circumstances not come into operation, or should an interruption develop itself in their course, the generative materials mature notwithstanding, and are separated, although no germs capable of development result therefrom. Examples of this in the vegetable kingdom, and in the lower classes of animals, as well as in fishes, amphibia, and birds, are too well known to require mention here.

On the other hand, in reference to mammalia and man, the case stood quite different. With respect to them, the formation of a germ was quite universally regarded as the result of coition; that act, in their case, being considered not only to have the design of rendering the female generative matter capable of development, but also of altogether producing it for the first time (creating it, *erst hervorbringen*.)

This opinion was of course chiefly based upon ignorance of the existence of the female generative material, the ovum, previously to coition.

So stood the matter, when, after centuries of controversy, Von Baer, at length, in 1827, discovered the ovarian ovum of mammalia and man, and at the same time, in its unexpected minuteness, the cause of its long concealment. I have always felt astonished that this discovery, in a department of science which has interested mankind in all ages in so extraordinary a degree, did not excite greater and more universal attention. By some it has been received, by some denied, taken no cognizance of by others; and only embryologists, in the strictest sense of the word, have occupied themselves with it, and they indeed only in its relation to the development of the embryo, and not with reference to the theory of generation in particular. This theory, which had so often been erected upon an hypothetical ovum, was so firmly based as even to suppress for a time the necessity of investigation as to how it might harmonize with what was founded on fact, after that very matter of fact became known. Although the existence of the ovum previous to, and independently of, all coition, was proved, yet coition was still held to be the sole and necessary condition to the maturation and extrusion of an ovum from the ovary; and all other circumstances, however distinctly they might indicate the contrary, were considered only from that point of view.

I was myself so much influenced by this theory, as to be led blindly by it in the course of my previous researches on the development of mammalia. They were, it is true, directed more particularly to the development of the fecundated ovum; but the process of fecundation was an essential object of them, and as I availed myself of a knowledge of the ovum, I certainly succeeded

in rectifying and throwing light upon several points which my predecessors had remained unacquainted with. Yet still I was always biased by the opinion, that the passing out of the ovum from the ovary, the first condition therefore of its development, must have in some way or other a necessary relation to copulation. Like all my predecessors I sought only to ascertain at what period the ovum freed itself from the ovary after the first act of coition in animals, and what was the part performed at the same time by the seminal fluid. I was so fortunate, although in this track, as to decide several of the most important questions; I furnished proof, that the male fluid comes into material contact with the ovum, and found by indubitable observations that the seminal fluid penetrates through the uterus and fallopian tube up to the ovary. Accordingly, in the acceptance of the old doctrine, I laid down the proposition, that the fecundation of the ovum of mammalia takes place upon the ovary, and in various kinds of animals at various periods after copulation, within which periods the seminal fluid advances up to the ovary, and the ova are extruded from the ovary.

Meanwhile, from continued observations and researches, I have now arrived at the conviction, that although the facts upon which I based that proposition are still perfectly correct, yet that nevertheless it by no means comprehends even the law of the development of mammalia and man, but that this latter is more comprehensive, and completely accords with the law governing the generation of all organised beings. This law is as follows:—

“Both in mammalia and in man, the self-forming ova undergo, in the ovaries of the female individuals, a periodical maturation, quite independently of the influence of the male seminal fluid. At this period, which in animals is usually called ‘the heat,’ in the human female, ‘menstruation,’ these mature ova disengage themselves from the ovary, and are extruded. At such time, also, the sexual impulse manifests itself in the female animal only, more particularly in woman. If copulation take place, by the material influence of the semen upon the ovum, the fecundation of the latter results. If copulation do not take place, the ovum is nevertheless extruded from the ovary,

and enters the fallopian tube, but there proves abortive, (*zu grunde geht*.) The relations in respect to time in this matter may vary, although, as it appears, to a different, but yet definite extent in different animals. The seminal fluid may have sufficient time to reach the ovary before the ovum leaves it. The ovum may, however, have already quitted it, and the seminal fluid first come in contact with it in the fallopian tube. The influence of the semen must, however, always be exercised within the tube, in order to produce development of the ovum, which, indeed, first commences its evolution within that duct. But only at this season of the periodical maturation of the ova can coition have fecundation for its result.”

I do not consider it necessary here to adduce proof of every element comprised in this law, inasmuch as many of them stand as already settled and familiar truths; but I shall in the next place restrict myself especially to proving, that at the time of heat, the ova in mammalia quit the ovary, and reach the fallopian tube, whether copulation take place or not, and whether the semen be conducted to the ovum or not. Previously, however, I would add the following observations.

The changes in the female genital organs of mammalia at the time of heat, which demonstrate their periodically increased activity at that season, have been partially known a long time. I may, however, mention in addition, that Barry and I both have drawn attention to the changes in the ovum also which are observable at this period, which may, therefore, be regarded as signs of its maturity. They relate in the first place to its size. The most mature ova are at the same time always the largest, which fact meanwhile bears out the law already announced by Von Baer and Valentin, and confirmed by me, in reference to the individual parts of the ovum, and the Graafian vesicle, viz. that the contained parts are always relatively smaller than the containing, in proportion as the parts are more mature. The vitellus is most full and most dense, and contains most vitelline particles, in mature ova. The number of the larger fat globules contained in it, which varies much in different animals, appears to decrease; and on the contrary, that of the smaller vitelline gra-

nules to increase. The germinal vesicle which, in the immature, is situated more in the centre of the yolk, is, in the mature ovum, found quite at the circumference, and sometimes becomes visible there, as though placed in a notch of the yolk; I have seen this in dogs. It may even be wanting in perfectly mature ova, and according to some observations made in dogs, it seemed possible that the disappearance of the nucleus of the germinal cell taking place previous to that of the cell itself, denoted the complete maturity of the ovum. The most striking, and most easily recognisable, at the same time a sure sign of the full maturity of the ovum, in dogs and rabbits at least, is afforded by the change undergone by the cells of the so-called discus proligerus, round about the zona, which commence to extend themselves into fibres, and being placed upon the zona in this form give a radiated appearance to the entire ovum. Lastly, I can decidedly assert with respect to the dog, that the formation of the corpus luteum in the form of granulation-like excrescences (*den granulationen ähnliche Wucherungen* (from the inner surface of the Graafian vesicle, commences previous to the opening of the latter, and the extrusion of the ovum, and may, therefore, also be considered as a sign of perfect maturity. These statements may I hope serve to guide others, in deciding the question in any given instance, as to whether they have mature ova, or such as are advancing to maturity, before them.

A repetition of the experiments made by Nuck, Haighton, Cruikshank, Grossmeyer, Blundell, and Hausmann, first, however, convinced me, that it is not the influence of the semen which causes the extrusion of the matured ova from the ovary: it may not be altogether unnecessary to quote and critically examine the results of those experiments in the next place.

Nuck (*Adenographia curiosa*, p. 69, op. omn. Lugd. Bat. 1773) put a ligature round the left cornu of the uterus of a bitch three days after coitus, and found, twenty-one days after, two ova in the portion of the uterus above the ligature, but none below it. Although this result is rendered very dubious by his addition, "*foetus jam consumptos et in materiam pene purulentam conversos fuisse*," although it is further certain

that on the 21st day after the first coitus the embryo of the dog is not yet formed, or scarcely in its first rudiments, yet still, if received to be correct, there is nothing in it to excite astonishment. The semen of the dog penetrates in copulation at once up into the point of the uterus; long before the third day after coitus it has entered the fallopian tubes; the ova also have already left the ovary and become fecundated, so that the tying of the uterus would only prevent the sinking down of the ova below the point of ligature: all the rest is readily explainable.

Haighton (*Reil's Archiv*. III. p. 46), divided the fallopian tube in a great many rabbits, both with and without a loss of substance, and sometimes on one, sometimes on both sides. In by far the greater number of instances he remarked a complete loss of sexual impulse afterwards: (probably because the vessels leading to the ovaries were also divided, whereby the maturation and development of the ova, and with that also "the heat" and sexual impulse, were arrested). When even the act of copulation was permitted by some of them, it proved ineffectual, and the ovaries had in most instances degenerated. Coitus and conception, however, took place in three instances in which he had divided the fallopian tube on one side only. He thence concludes, that the ovaries might become affected by the stimulus of impregnation, without contact with the seminal fluid, whilst he should have been content to rest on the assertion that the ova quit the ovary, even when the semen cannot reach the latter. In one rabbit, in which he had divided the fallopian tube on one side six hours after coition, he subsequently found corpora lutea on both sides, but ova on the uninjured side only. This may also be easily explained; indeed, in two ways. In the first place, Barry and I have seen the semen in the rabbit upon the ovary within nine and ten hours after coition. It is, therefore, quite possible that within six hours it might have already passed the point of ligature. The ova consequently might have been fecundated, and a tubal gestation have been produced. If, however, this view be not received, then, in the second place, the mature ova may have been extruded on that side on which the semen could not reach them, but there proved

abortive because unfecundated, while at the same time corpora lutea were formed just as well as on the opposite side.

The experiments of Grassmeyer (*De Fecundatione et Conceptione Human.* Dissert. Götting. 1789, p. 48) are less to be relied on, and no conclusion can be drawn from them. He placed a ligature round the fallopian tube, or the uterus, in fourteen rabbits; after which simple operation only two survived,—a proof that the operation was badly conducted. One of these two animals, in which he had tied the fallopian tube, was with young at the time of the operation, and in consequence aborted. Four days afterwards sexual impulse was ardently exhibited, and the act of coition consummated. On killing the animal fourteen days later, he found the cornua of the uterus in some parts somewhat swollen, but no ovum and embryo, and likewise nothing worthy of remark in the ovaries. In the abdominal cavity, however, he found hydatids, which he looked upon as something very extraordinary, although Blumenbach pointed them out to him as being such. In the other rabbit the fallopian tube was also tied. It is represented as having become impregnated twenty-one days afterwards, although Grassmeyer did not see the act of coition; and nine days subsequently found no change whatever, either in the ovaries or in the uterus.

Cruikshank also made an experiment bearing on this point, but which was without result. He placed a ligature around the left fallopian tube of a rabbit, close to the uterus, a day after coitus. After fourteen days he found the uterus of the right side without embryo, although the placenta was perceptible, and had retrograded in the process of formation; the same was the case with the ovary. On the left side was no sign of fecundation in the uterus, no placenta, the tube very wide and soft, the ovary twice as large as that of the other side, red, and covered with coagulable lymph. In the fallopian tube was seen an hydatid, which contained a clear fluid, but no embryo. In addition to this there were general traces of peritonitis and exudation in the abdominal cavity. In this instance, according to my experience, the fecundation and extrusion of the ova must have taken place within twenty-four

hours. It appears, however, that the operation had excited violent inflammation, and that from this cause the ova on both sides had aborted, though, on the right side, development had advanced somewhat farther (*Philosophical Trans.* 1797, vol. i. Experiments 11 and 16.)

Blundell (*Medico-Chir. Trans.* vol. x. p. 264, 1819; *Meckel's Archiv.* v. p. 422; *Principles and Practice of Obstetrics*, Lond. 1824, p. 60) found, after division of one cornu of the uterus in rabbits, prior to and after coition, ova only in the uninjured cornu, but corpora lutea, which were not distinguishable from each other, on both sides. After division of the vagina, ova were never found in the uterus, but still corpora lutea in the ovaries. At the same time he remarked an insatiable desire for copulation after these operations.

Lastly, Hausmann (*Ueber die Zeugung des wahren weiblichen Eies*, p. 93), in his 53d experiment, on a sow, in which he had removed the fimbriae of the fallopian tubes from contact with the ovaries, saw no fecundation, but still the development of corpora lutea followed. A second experiment (54), in which he did the same with only one ovary, is not to be relied upon.

The following are the experiments which I have myself made in reference to this subject:—

On the 29th of January, 1842, at half-past 8 A.M., I permitted a rabbit to receive the male; the spermatozoa were present in the vagina in large quantity. At half-past 2 P.M., after six hours therefore, I opened the animal, and cut out its right ovary and fallopian tube; in doing which, I found that this was one of those rabbits from which I had removed the uterus in the previous summer. The ovary and fallopian tube, notwithstanding, exhibited all the signs of "the heat," were injected with blood and turgid; several Graafian vesicles were much swollen. The ciliary motion on the epithelium of the tube was very active; the latter, however, naturally enough, contained no spermatozoa. I proceeded to examine the four largest and most swollen Graafian vesicles, and found them still closed, with an ovum in each one. The cells of the *membrana granulosa* were much developed, and those of the *discus proligerus* extended into fibres, as I have always observed to be the case in

those ova which are designed for the immediate act of fecundation. The yolk of one ovum had a spotted appearance, which was not the case with the others. A germinal vesicle was no longer discoverable in any of these four ova, in spite of the greatest care and attention. The ovum from the largest Graafian vesicle measured in the diameter of the discus 0,0100 (Paris inch); of the zona, 0,0060; of the yolk, 0,0045. The zona itself was 0,0006 thick.

I killed this animal at half-past 6 P.M., ten hours therefore after coitus; at which period, in other instances, the ova have always left the ovary. The uterus of the other side had also been removed, and the fallopian tube and the ovary had become adherent. But notwithstanding this, in the latter were several Graafian vesicles, much swollen, which, however, still contained ova; and in three of them the cells of the discus exhibited their spindle-like metamorphosis even yet. The yolk of each of these was spotted very dark, which appearance, however, was not produced by any formation of cells. It rather appeared to me as though a retrograde metamorphosis were already going on in the yolk, which was probably caused by the general condition of the ovary. Some other Graafian vesicles, for instance, which were not much swollen, contained some of those ova with a darkly spotted yolk, in which both the cells of the membrana granulosa, and of the discus, were changed into dark granules. In the ova of this side, also, I could no longer find germinal vesicles. Neither of the ovaries exhibited any corpora lutea.

On the 22d April, 1841, I cut out both uteri, leaving the ovaries and tubes, from a rabbit which was eight days gone with young. The animal soon recovered perfectly, and I therefore, on the 22d of June, placed it again with the male. The sexual desire of the doe was so strong, that it not only permitted coitus immediately, but during the intervals imitated the act upon the other does. Four days afterwards I killed it. I found on the left ovary three, and on the right five, recent corpora lutea, and in addition a Graafian vesicle filled with black coagulated blood. Satisfied with this result, I unfortunately only examined the tube with reference to ciliary motion,

which it exhibited very strong and perfect.

In the summer of 1841 I had excised the uterus of the right side from another rabbit, leaving the fallopian tube and ovary. This animal subsequently exhibited strong signs of being "at heat," drove the other does about, mounted on their backs, and so on. Notwithstanding this, so often as I placed it with the buck, it would not permit the act of copulation to be effected: such was the case on the 15th and 16th of May, 1842. I had quite forgotten the former operation upon it. I allowed it to remain with the male unnoticed from the 17th to the 21st of May, and on the latter day made use of it for another experiment.

I now found to my surprise the traces of the operation; and, in addition, that coitus had notwithstanding taken place.

In the upper portion of the left uterus I found an ovum, which attracted notice from its slightly swollen and transparent condition. The stage of its development corresponded to that usually observed in the ova of rabbits about the 9th day. The ovary exhibited a corpus luteum. The right uterus was wanting, and the lower end of the tube was adherent to the lower portion of the excised uterus, and both were closed. Between them was a thick cheesy mass, which, when examined under the microscope, exhibited pus globules, and within which the ligatures made use of in the operation were inclosed. The ovary presented four corpora lutea, just as perfectly developed as that of the left side. It occurred to me to examine the fallopian tube, and I unexpectedly found the four ova in the centre of it. They had manifestly advanced a certain extent in their development, had then remained stationary, and were now on the point of aborting. The discus proligerus had disappeared, and in its place a slight layer of albumen had formed around the zona; the latter was somewhat swollen. The vitellus did not completely fill the zona, and clearly shewed signs of resorption. It was irregular, very pale, granular, and small. Some darker granules were remarkable in the yolk of one of the ova.

On the 19th and 20th of January, 1843, I removed, in four portions, both the uteri (with the exception, as will afterwards appear, of a small por-

tion at either end of each) from a Pomeranian bitch, which had been lined three weeks previously; they contained five ova. The animal bore the operation very well; and as my intention was to let it live, I brought all the ligatures out at the external wound, which was closed by suture. It was soon quite well, the ligatures came away, and the external wound closed. I then took the animal to live in the house, where it became lively to a remarkable degree, and grew large and fat. A certain sensibility of the belly on pressure, which had existed, also disappeared, and in a short time not the slightest trace of its having suffered any thing could be remarked.

On Sunday, the 14th May of the same year, I first observed the dogs begin to follow her. She bit them off, however, in a playful manner, and continued very lively until Wednesday, when the external genital organs were much swollen, and secreted blood in a considerable quantity. On this day the animal became dull, and ate nothing; but on the next it became again very cheerful, and the dogs were still more zealous in following her about. She would not, however, permit the act of coition, until on the evening of the 20th, when it took place in my presence, and continued during three-quarters of an hour. From that period she permitted herself to be lined daily by different dogs, through the whole following week until the 28th. On the 29th also she was willing, but the male did not accomplish the act. I was very undecided as to the time at which I should examine the animal. I was convinced that the ova would have separated from the ovaries, and have entered the fallopian tubes. I further expected that they would abort there; but I much wished to wait until the period when, in the regular course of things, a division of the vitellus should have commenced, in order that I might see whether perhaps some trace of such division might not make its appearance, as is often the case in the unfecundated ova of frogs and fishes. My reason for allowing the animal to live so long was, because this division first commences in the lower portion of the tube, and bitches generally permit themselves to be lined until the period when the ova are on the point of entering the uterus. As, however, that

inclination had continued in this case already eight days, I was in fear for the ova, and had the animal killed at ten o'clock on the 29th.

On opening the abdomen, the traces of the previous excision of the uterus were on the whole but slightly marked. The bladder adhered anteriorly to the cicatrix in the abdominal parietes by a sort of mesentery; all the other organs were free from such adhesions. The great omentum was completely united with the remains of the uterus and its mesentery, as also with the investing membrane of the left ovary, and altogether enveloped in a peculiarly complete manner the entire alimentary canal; the latter, however, was throughout quite freely moveable. With regard to the organs of generation, the vagina, the os uteri, and body of the uterus, were perfectly normal in condition. There remained attached to the body of the organ, on the right side, about an inch, and on the left half an inch, of the cornu of the uterus, which likewise were perfectly normal, and both completely closed superiorly. On the right side a callus-like portion of cicatrix-material (*Narbensubstanz*), two lines in length, connected, in direct continuation, the lower portion of that cornu of the uterus to the upper portion of the cornu, more than an inch in length, and having the ovary and fallopian tube attached to it, both of which were quite normal, and had acquired no adhesions. The left side presented a larger portion of this cicatrix-material, and between that substance and the omentum the most complete adhesion had been formed: with that material the upper portion of the left cornu, with ovary and tube attached, was continuous as on the other side; the upper portion of this cornu, however, was somewhat distended, and contained pus. The ovary and tube were quite normal.

My first investigation was with respect to the seminal fluid; and I found spermatozoa in the body and both the lower portions of the two horns of the uterus; on the whole, however, but few. They were no longer in motion; which fact, as well as their scarcity, astonished me in some degree, as the bitch had been lined only the day previous. There was not the slightest trace of spermatozoa to be found in the upper portion of the right uterus, after

the most minute search; the pus on the left side made the examination both impossible and unnecessary.

The ovary of the right side exhibited two, and that of the left four, quite perfectly developed, fresh and large corpora lutea. They did not in any point differ from the corpora lutea of other bitches on the eighth day after coitus: they were quite as large, quite as much injected and flesh-coloured in appearance; they presented in their interior precisely the same structure and radiated texture, and contained also a small central cavity, filled with a transparent gelatinous mass. The surfaces of most of them were smooth, only one exhibiting a kind of opening; such an opening is, however, rarely met with in bitches on the eighth day, and is in most instances already closed, without even a trace of its appearance. Lastly, both ovaries still contained most distinctly the five corpora lutea of the last gestation in January, in the form of lenticular yellow masses.

I next examined, in the most careful manner possible, both fallopian tubes, and the upper portion of the right uterus, for the ova. Unfortunately, however, I found none. I do not think that I could have overlooked them, even although they might have already undergone an essential change in appearance. On the other hand, I am nevertheless convinced, from the condition of the corpora lutea, and from my experience with rabbits, that the ova had already left the ovary, and had entered the tube, perhaps even the uterus, and had there aborted for want of fecundation. I ought to have made the investigation earlier, on the third or fourth day, and not have left it until the ninth.

On the 14th August, 1842, I opened the abdomen of a bitch, supposing her to be with young, but found such was not the case. I then put a strong ligature around the left uterus, at about its middle, cut off the ends of the ligature, and the animal recovered.

Monday, the 4th of January, 1843, at nine o'clock in the morning, this same bitch was lined, and again on the following day, by two dogs.

Friday, the 13th January, I had her killed. In the middle of the left uterus, at the part where the ligature was applied, there was a swelling of the size of a walnut, to which the omentum was

firmly adherent: a small portion of the organ above the ligature retained its normal diameter, but the upper end of it appeared very much stretched, and expanded into a fluctuating sac, almost as large as a hen's egg, into which the fallopian tube conducted. The right ovary presented three corpora lutea, the left four quite as perfectly formed as the others. I first examined the right uterus, and found the three ova, one about the middle, the second about an inch from it, and the third above, in the point of the uterus. They presented that state of development at which the germinal membrane is just commencing to form itself from the vitelline globules, and which I will describe more precisely in another place. On the left side I unfortunately examined the fallopian tube in the most careful manner in vain—I could find no ova. Meanwhile, since they had certainly been extruded, as the four corpora lutea proved, I think that they had passed through the fallopian tube, and had reached the sac-like expansion of the uterus. This, however, was filled with a stinking green pus (the swelling at the point of ligature also contained some), necessarily rendering all search after the ova impossible.

[To be continued.]

ANALYSES AND NOTICES OF BOOKS.

“L'auteur se tue à allonger ce que le lecteur se tue à abréger.”—D'ALEMBERT.

A Treatise on Poisons in relation to Medical Jurisprudence, Physiology, and the Practice of Physic. By ROBERT CHRISTISON, M.D. Professor of Materia Medica, &c. in the University of Edinburgh. 4th Edition, 1845, 8vo. pp. 986.

WE have the pleasure of announcing to our readers the appearance of the fourth edition of this valuable treatise. Its character is so well established as a standard work in the medical literature of this country, that it needs no encomium from us. For the benefit of those of our readers, however, who feel an interest in the progress of toxicology, it may be advisable to give a cursory notice of some of the important additions which have been made by the distinguished author.

It is now fifteen years since the first

edition of this work appeared, and it is only doing justice to it to assert, that it has uniformly maintained its popularity as a work for reference and practice. It has for a long period been in the hands of barristers, who have not failed to make good use of it in the cross-examination of medical witnesses; and we believe that there are now few medical men who venture into the witness-box on a trial for poisoning without having at least consulted it respecting some point on which their evidence is likely to be impugned.

One circumstance which we admire in Dr. Christison as an author is, that he is not an advocate of "finality" in reference to toxicology. Many changes have taken place in the science, many old views have been exploded, and new doctrines introduced, since the appearance of his first edition. But although some of these doctrines have not coincided with his original opinions, he has not hesitated to adopt them where they have been founded on good and sufficient reasons; nor has he hesitated to acknowledge, in candid language, the alteration which has taken place in his opinions. Another circumstance to admire in him is, his fairness as a writer in acknowledging all that he has derived from other sources. His example shows, that it is no disgrace to a man to borrow largely from his contemporaries. His references are numerous, and for a large number of the facts contained in his volume he acknowledges his obligations to others. Indeed, that individual can have but a very slight notion of the subject of toxicology who supposes that any writer can compose a work on this science from facts falling within the range of his own experience and observation. He would, indeed, be a fortunate person who, from his own practice alone, could bring together all the facts necessary for elucidating the medico-legal history of any one poison.

The matter which has been added to this work since its first appearance may be judged of from the fact that this edition contains nearly three hundred pages more than the first—it now extends to nearly one thousand pages. The greatest additions appear to have been made to the sections on arsenic, mercury, lead, and some other irritant poisons; but the whole work has undergone revision. We can trace

the revising hand of the author from the first chapter on the "physiological action of poisons."

Dr. Christison, after having stated that toxicologists of late years have been disposed to regard the action of poisons as depending exclusively on absorption, and that numerous experiments have certainly shown that this process is carried on much more rapidly than was formerly believed, proceeds to examine the results obtained by Mr. Blake. This gentleman, it must be remarked, denies that poisons act by sympathy, and alleges that all their effects are due to absorption. In some of his experiments he succeeded in showing that certain substances susceptible of analysis had been carried into the blood in the course of a few seconds. At one time toxicologists were all advocates of "absorption," then "sympathy," and now the current is again strongly setting in favour of "absorption." As it has thus become fashionable to pass from one extreme to another, we shall quote the plain common-sense judgment which Dr. Christison passes on Mr. Blake's views.

"For example," he says, "they (Mr. Blake's experiments) do not shake the validity of these observations, in which it appeared that an interval, inappreciable or barely appreciable, elapsed between the application and action of hydrocyanic acid and of conia. Mr. Blake, indeed, denies the accuracy of these observations, insisting that in those he made himself with the most potent poisons, he never failed to witness, before the poison began to act, an interval considerably longer than what had been observed by others, and longer also than what he had found sufficient for the blood to complete the round of circulation; that, for example, the woorari poison, injected into the femoral or jugular vein, did not begin to act for twenty seconds, conia and tobacco for fifteen seconds, and extract of nux vomica for twelve seconds, and that hydrocyanic acid dropped on the tongue did not act for eleven seconds if the animal was allowed to inhale its vapour, and not for sixteen seconds if direct access to the lungs was prevented by making the animal breathe through a tube in the wind-pipe. But Mr. Blake cannot rid himself thus summarily of the positive facts which stand in his way. Duly

weighed, the balance of testimony is in favour of those whose accuracy he impugns. For, in the first place, they had not a theory like him to build up with their results, but were observing, most of them at least, the simple fact of celerity of action. Then their result is an affirmative or positive statement; his merely a negative one: they may perfectly well have observed what he was not so fortunate as to witness. And, lastly, it is not unreasonable to claim for Sir B. Brodie, Dr. Freer, Mr. Macaulay, and Mr. Taylor, all of them practitioners of experience, the faculty of noting time as accurately as Mr. Blake himself. As for my own observations, I feel confident they could not have been made more carefully, and that I had at the moment no preconceived views which the results upheld, but, if any thing, rather the reverse."—P. 10.

Dr. Christison considers that the question is still left unsettled, and that it is almost beyond the reach of experiment.

At p. 70 we find detailed an interesting case of poisoning by monkshood, which occurred lately to Dr. Geoghegan, of Dublin. It involves the question as to how far a medical jurist is justified in pronouncing an opinion on death from poisoning when no poison can be discovered either in the food or body of the deceased. It is a favourite doctrine with some, that the only proof of poisoning which a court of law ought to receive is the production of the poison itself. It might be just as well laid down that no conviction for death from criminal wounding should take place without the production of the weapon. If such a rule were adopted, it would be very convenient for one class of murderers, who might select poisons not susceptible of chemical analysis, and set the law at defiance. Dr. Geoghegan did not hesitate to give an opinion against the accused in this important case, and the correctness of this opinion was afterwards confirmed by the confession of the woman before execution. The poison which she used was the powdered root of monkshood. This case is well worthy of attention, as it shows clearly that chemical evidence is not always necessary to the proof of poisoning, nor to a conviction for murder by poison. As Dr. Christison remarks—"great caution must be

observed in applying the principle here inculcated. But the opposite doctrine, that no charge of poisoning can be established without the discovery of poison in the body or in the evacuations, appears to me a great error, though upheld by no mean authority. Under that doctrine few criminals would be brought to justice were they to resort to the variety of vegetable poisons, which, in certain seasons, are within the reach of every one."—P. 72.

The tests for the various poisons have been carefully revised, but we find nothing requiring particular comment. In respect to arsenic, it has been lately the custom to depreciate the reduction test; but we quite agree with the author when he states, "that the appearances exhibited by a well-formed arsenical crust, even in the minute quantity of the 300th part of a grain, are imitated by no substance in nature, which can be sublimed by the process for the reduction of arsenic." (p. 260.)

There is much sense in the following remarks:—
